An escape from a poverty trap and the role of entrepreneurship: Microfinance lending to the ultra poor in the Northern Bangladesh

August 27, 2020

Seiro Ito[†], Takashi Kurosaki[‡], Abu Shonchoy[§], Kazushi Takahashi[¶]

Abstract The existing microcredit programs rarely lend to the ultra poor people. With a randomised controlled trial in a rural, low income setting of northern Bangladesh, we assess the creditworthiness of the ultra poor and suitable debt contract design to help them invest and escape from poverty. We use a stepped-wedge design over the key features of loans, i.e., small-scale sequential disbursement vs. lumpy upfront disbursement, with vs. without a grace period, and cash vs. in-kind loan with a managerial support program. Compared with the traditional, Grameen-style microcredit, the provision of large, upfront liquidity increases both repayment rates and net asset levels. This is consistent with the existence of an asset-based poverty trap which can be overcome by increasing the loan size. Provision of a grace period does not change the repayment rates or asset levels. It is also shown that managerial supports induce participation of less experienced and poorer households to microfinance without affecting the repayment and asset accumulation. For all households, labour incomes become larger towards the end of loan cycle, which we interpret as evidence of repayment discipline. Our main findings, a large, upfront disbursement results in faster asset accumulation that is suggestive of an escape from a poverty trap and managerial support programs induce the participation of the ultra poor, are generalisable to other rural areas that are suited to livestock production.

Revisions

Title and abstract:

1. Dropped: Given the lack of alternative lenders in the area, we argue that the high repayment rates need not generalise to other contexts.

Introduction:

1. Still in need of a reference for the Prof Yunus' claim.

Existing studies:

1. Dropped: Fortunately, our program ended with relatively low delinquency rates compared to other programs, and there is even suggestive evidence of repayment discipline among the borrowers.
2. Dropped more detailed description of results and changed to:

   By complementing this result with the fact that borrowers purchase cattle only when large upfront liquidity is provided, we conclude that there is a poverty trap.

Study sample:

1. Added the whole section. Moved rejection contents from Experimental design section. Added attrition description.
2. Describes sampling and summary statistics.
3. Needed: Statistical, not descriptional as in Background section, information about chars.
4. Added:

   Using a Landsat imagery, we identified 128 *char*s within a day boat ride from the Gaibandha peer and collected information by filed visits. From this list of *char*s, we randomly selected 80 *char*s.
5. Added: TABLE 1 (descriptive statistics of sample households) and its description.

   TABLE 1 shows descriptive statistics of sample households. As we randomly allocate them into four different arms, traditional, large, large grace, and cattle, summary is shown by the arms. As shown in the Appendix, these baseline household characteristics does not differ statistically between the arms. Our sample is characteretised by relatively low literacy rate (HeadLiteracy) and relatively young age (HeadAge) of the household heads. Literacy rate is lower than the national average of adult males at 61.54% in 2012 (UNESCO). Household size (HHsize) is not large, around 4.1-4.3 members, due probably to the constant flood threats, as indicated by above 40% exposure at the baseline (FloodInRd1), that do not easily allow a large household formation. Cattle holding per household (NumCows) shows cattle rearing is not common and the mean herd size is between .2 to .3. Mean net asset values per housheold (NetValue) differ between the arms, but they mostly reflect sampling errors as indicated by the large standard deviations. Attrited indicates attrition rates in the household survey, and GRejected and IRejected show group rejection rates and individual rejection rates to the lending program, which happen separately from survey attrition. We will analyse attrition and rejection later in Section VII.1, but at this point, we just note that the attrition rates are not statistically different between the arms. Active indicates the nonattrited borrower ratios. Because there are more rejecters in the traditional arm, active member ratio is smaller.
6. Added to clarify the difference between rejection and attrition:

   While loan rejecters remained in our sample, we lost four groups to floods in 2013. As they relocated, we had no choice but to drop them from the study. In our study, attrition refers to a household drop out from our survey. Rejection refers to a loan rejection in our intervention, and majority of rejecters (81.25%) did not attrit from our household survey.

Also in the TABLE 1 footnote:

Because attrition and rejection are separate events, a household can reject and attrit, so active members $\geqslant$ total - (rejected members + attrited members).

Experimental design:

1. Moved to Study sample section: Rejection contents.

Results:

1. Participation and attrition are separated as two subsections.
2. Added to clarify the difference between rejection and attrition:

   We analyse nonparticipation in relation to the debt contract design that they were randomly allocated to.
3. Consolidated 3 tables in the appendix to TABLE 3, consolidated 2 tables in the appendix to TABLE 4.
4. Attrition subsection only refers to the appendix, not to any of its tables.
5. Changed to:

   These features that are plausibly disadvantageous in rearing a heifer notwithstanding, the cattle arm with training induced partcipation.
6. Added:

   Contents of IGAs are cattle, goat/sheep, growing cereals (paddy, corn) and nuts, small trades, and house and land leasing.
7. Reorganised: Previously, Figure 7 was missing. In addition to impact estimates in error bars (FIGURE 2, FIGURE 6, FIGURE 8), we show IGA contents with CATTLE HOLDING BY ARM (FIGURE 3), ALL IGAS (FIGURE 4), CONTENTS OF FIRST IGA (FIGURE 5).
8. Changed cattle holding description:

   FIGURE 3 shows more detailed changes in cattle ownership by arm. Holder rates are the number of cattle owners per arm size, holding size is average holding per owner, initial owner holding are herd size for owners who held cattle at baseline, and per capita holding is mean cattle holding in each arm. Initial owner holding and holder rates show impacts on the intensive and extensive margins, respectively. Per capita holding tracks impacts on both the intensive margins (growth of initial owners) and the extensive margins (growth of new owners). All the indicators are similar across arms at the baseline.

   We see that the holder rates increased in all arms, but the increase was smallest for the traditional. This shows that, even the small upfront lending of traditional arm helped increase catte ownership but to a lesser degree. Without equally large upfront liquidity and the repayment installments that began immediately, a smaller fraction of borrowers could purchase their first cattle. Holding size increased in all non-traditional arms, while the traditional arm remained stagnant. It is also the traditional arm that has the smallest, or negligible, impacts on the initial owners. [These initial owners, overall, diversified their portfolio rather than increasing the cattle investments.] Initial owner holding size is larger than the average holding size per owner for the non-traditional arm, indicating the higher returns to members with experiences. The per capita holding growth was smallest in the traditional arm. This is due to smaller impacts on the extensive margins (fewer new ownership, smaller growth by new owners) and little impacts on the intensive margins (negligible growth by initial owners).

9. Added:

    FIGURE 5 shows the first IGAs of members. The first IGA is defined as the oldest IGA for the household. For most of the households, the oldest IGA had started after the baseline, and it is the IGA with the largest cash flow. Of course, there are a small percentage of households with an existing IGA before the baseline, but, with randomisation, the fraction of such households are similar across arms. Therefore, the between arm comparison of the first IGA gives us an idea about how the households had chosen the initial investments. In the traditional arm, there are 33 borrowing members who report cattle as their first IGA, and 76 borrowing members (69.72%) who report other than cattle as their first IGA. This contrasts with the non-traditional arms that 466 borrowing members who report cattle as their first IGA and 25 borrowing members (5.09%) other than cattle as their first IGA. As can be seen from FIGURE 4, for the 2nd and 3rd IGAs, a diversified IGA portfolio is continued to be held by all the traditional arm borrowers, and only the minority of non-traditional arm borrowers has a diversified portfolio.

10. Added:

    The low repayment rates among traditional arm borrowers may be due to our experimental design that a new loan is disbursed unconditionally up to three cycles, lacking the dynamic incentives to repay.

    But we also need not to stress this too much because we are finding some repayment discipline among the non-traditional borrowers that they try to repay with increased labour incomes and suppressed consumption.

11. Added:

    We also observe that impacts on all outcome measures are not statistically different between the poverty classes (see Appendix E).

12. Added:

    In summary, we found that our managerial support programs induce the members of disadvantaged background to participate in microfinance, achieving the further outreach with the impacts that are no different with other borrowers. This is consistent with the finding of the previous studies that a certain level of skills is necessary for participation, and our managerial support progams supplemented the lack thereof. We observed that the upfront loan disbursements have allowed borrowers to invest in cattle while members with sequential disbursements mostly opted for smaller livestock and small business trades. In combination with a greater return to cattle on net asset accumulation and a greater rate of loan repayment, we consider it as evidence of a poverty trap and an effective measure to break it. We also found the impacts and repayment rates are indistinguishable between the moderately poor and the ultra poor.

Appendix:

1. Keep only impact estimation tables referred in the main text.

Contrasts with Balboni et al. (2020)

Balboni et al. (2020) collect data from transfer recipients and control group of BRAC's TUP. Using the recipient data, they estimate the equation of motion $K_{t+1} = \phi(K_t)$, show the S shape, and compute the threshold asset level $\hat{k}$ that separates the low and high equilibria. They then show that individuals who are above $\hat{k}$ increase the assets while individuals below it decrease them. The variations of initial asset level allows the identification of bifurcation as these variations effectively allocate inidividuals to below and above the threshold. Anticipating the endogeneity of initial asset levels to asset growths, they show that initial asset levels have no correlation with post intervention asset growths after conditioning on the above-threshold dummy. This is suggestive evidence that the unobservables that correlate with initial asset levels are exogenous to post-transfer asset increases.

In the poverty trap dynamics, the key is the low returns among the low k holders. The returns to high k holders are qualitatively similar in the covex and concave production functions so long as they are above the 45 degree line. Why are they low? Authors show the baseline vehicle ownership is statistically smaller by 4% (but not for other assets, total assets are not tested) for the below threshold households, and the differences relative to the above threshold households grew after the transfer receipt. They conclude that the complimentary assets serve as the fixed inputs of production, and the lack thereof withholds households from escaping the poverty trap.

their strength Large sample size, precise asset and labour data, direct estimation of equation of motion, and associated tests of multiple equilibria.

our strength Experimental variations in contract design (Upfront, support programs), use of IGA information that allows the (poverty trap) interpretations without structural estimation, reference to market costs/prices.

Contrasts with Banerjee et al. (2019)

Banerjee et al. (2019) use regionally matched-pair data under staggered branch opening of an urban MFI. They divide the sample into borrowers with a prior business experience (GE) and others (non-GE), and show that impacts are persistently positive for GE borrowers but not for non-GE borrowers. With structural estimation, given a talent distribution, they interpret this as evidence of a poverty trap through a liquidity constraint. They also note the impact heterogeneity is due to MFI selection but not talent heterogeneity, as pre-MFI entry businesses are more profitable than post-MFI entry businesses of the same firm age.

their strength Urban setting, contrast of long-run versus short-run impacts, data on business outcomes, gross substitute/compliment with demand for informal loans, explaining the lack of average impacts by finding the subpopulation with superior talents and contrasting with other subpopulation.

our strength Ultra poor population, rural and fragile setting, selection on entrepreneurship without affecting outcomes, Upfront leads to faster asset accumulation and higher repayment rates.

What the three papers agree

- A need for larger lending than regular MF.
- Existence of a poverty trap.
- Evidence of a nonconvex production set as a source of poverty trap.

Contents

I Introduction

Since the microcredit became popular in Bangladesh in the late 1980's, the number of borrowers increased rapidly throughout the world. According to over 3700 microfinance institutions (MFIs), there are estimated 204 million borrowers around the world in 2013, of which 110 million are the poor borrowers whose incomes are below the national poverty line (Microcredit Summit Campaign, 2015). The outreach to the extremely poor population or the *ultra poor*, however, is arguably slow in comparison.[*1]

There are demand and supply side reasons behind the slow outreach to the ultra poor. On the demand side, the ultra poor borrowers may not be entrepreneurial enough to demand credits for production, or may face an inferior production possibility than the wealthier borrowers. On the supply side, MFIs may perceive the ultra poor as riskier than the moderately poor, or their loan size may be too small to justify the fixed transaction costs while the lender is constrained to keep the interest rate low to avoid adverse selection and moral hazard.

As the rigorous evaluations of microfinance progress, it has become clear that the impacts are not uniformly positive. A group of influential research has shown that only a subgroup of borrowers, those with prior experiences or high ability, have positive returns from borrowing (Banerjee et al., 2015c; McKenzie, 2017; Buera et al., 2017; Banerjee et al., 2019). This is in a stark contrast to the popular belief in microfinance that anyone can become a successful borrower.[*2] Logically, there must be some minimal level of entrepreneurship to participate and continue as a borrower in any form of finance. Then, the question is, what sort or how much of entrepreneurship is required in microfinance?

To shed light on the required level of entrepreneurship, we took this question to the Northern Bangladesh where a flood threat limits the leading production process to be least complex: livestock rearing. There are residents who own livestock so its know-how is semi-public knowledge. The required entrepreneurship, then, is to gather all the pieces of information, decide to raise livestock, form a production and a sales plan, and implement. This is the definition of entrepreneurship we use in our paper. In our intervention, we provided a heifer to a selected subgroup of participants as an in-kind loan and bundled it with training and consultation services to make sure the borrower has the right cookbook to follow. Under this treatment, the entrepreneurship to decide what to invest and how to come up with a solid plan is no longer a necessity.

In our study, we compare the borrowers who were provided with such knowledge and the managerial supports with the borrowers who were not. By randomising the offers, we identify the causal impacts of not requiring the entrepreneurship on both the participation and the outcomes. We find that our managerial support program, that renders entrepreneurship redundant, induces residents with fewer experiences in livestock production and a lower asset level to participate while keeping the mean outcomes the same as in the comparison group.

There is yet another motivation for our study. In bridging these two arms that are different in multiple aspects, we introduced intermediate arms. At the end, we were left with an arm of conventional microcredit that disburses small upfront liquidity for three times, and several arms with large upfront liquidity that disburse the equivalent total amount once under three period maturity. This gives an

[*1] MF is not successful in reaching out to the poorest of the poor, or the ultra poor (Scully, 2004). Empirical evidence in Yaron (1994); Navajas et al. (2000); Rahman and Razzaque (2000); Armendáriz-Aghion and Morduch (2007) supports this claim. Some authors discuss the tradeoff between sustainability and outreach for microfinance institutions (MFIs) Hermes and Lensink (2011); Hermes et al. (2011); Cull et al. (2011).

[*2] A leading proponent is the nobel laureate Professor Mohammad Yunus who claims that "we are all entrepreneurs." [Abu-san: Can you get a reference for this in the BibTeX format? I have a 2017 Guardian article quoting https://www.theguardian.com/sustainable-business/2017/mar/29/we-are-all-entrepreneurs-muhammad-yunus-on-changing-the-world-one-microloan-at-a-time]

opportunity to test if frontloading the liquidity, while keeping the total loan size and maturity equivalent, matters in the future asset levels. If the production technology is nonconvex and if there is a credit constraint, it gives rise to a poverty trap which can result in larger asset accumulation when provided with large upfront liquidity. While we do not directly test for a poverty trap, the investment choices strongly indicate its existence: Only borrowers without a frontloaded loan opted for smaller, multiple investments. Our experimental design tests if frontloading the liquidity breaks a poverty trap, under the assumption that there is one, and found that upfront liquidity results in larger asset accumulation without affecting the repayment rates.

Our study follows the literature of microfinance debt contract design as hallmarked in Field et al. (2013) who found a grace period induces more risk taking and subsequent loan delinquency. Under our setting of limited production choices, it is irrational to invest in riskier assets, such as goats, when the designed grace period suits the heifer cash flow and a heifer's risk-return profile is considered to be Pareto-dominating. A strategic default is also more difficult in our setting because the number of formal credit suppliers is limited, which is probably zero,[*3] and relocation requires a costly boat ride and financially reliable mainland contacts. The repayment rates in our study turned out to be no lower than the comparable microfinance schemes (Banerjee et al., 2015a).

Our study is closely related to a large scale cattle transfer study conducted in the neighbouring area (Bandiera et al., 2017; Balboni et al., 2020). The targeted population of their study is similar to ours, yet our study population resides on less stable terrain, are more exposed to flood and water logging, are considered to be less well connected to the market, are equally less trained, and are probably poorer. The chance of survival for each investment project is expected to be no higher. More prominently, our study is commercially oriented: It uses a loan than a transfer, and charge market level fees to all the services provided.

We consider our finding is generalisable to rural areas where small scale livestock production is prevalent. While there is a caveat that the domain of our results is a low level herd size and the entrepreneurial capacity to hold a larger herd size can be different from what our study suggests,[*4] the successful livestock transfer program in the neighbouring areas (Bandiera et al., 2017; Balboni et al., 2020) and our results indicate that supporting asset accumulation through large livestock has wide applicability in assisting the rural ultra poor to escape from poverty.

In the following section, we summarise the existing literature. Section II gives the link to the previous literature. Section III gives the brief account of background of study site. Section V lays out the details of experimental design. Section VI explains the estimation strategy. In section VII, we provide the experimental results and contents of income generating activities (IGAs). Section VIII shows a possible mechanism of poverty trap that our target population is under. Section IX discusses the interpretation of results.

II A brief review of existing studies

There are four aspects in our study that relate to the existing literature: The role of entrepreneurship in microfinance impacts, variations in debt contract design, empirical assessment of a poverty trap, and targeting the ultra poor. We will discuss these in turn.

Much has been discussed about the poverty reduction impacts of microfinance in the early days of microfinance studies (Morduch, 1999). Recently, doubts are cast on the magnitude of microfinance impacts (Banerjee et al., 2015a; Duvendack and Mader, 2019; Meager, 2019) while asset grants (capital injection) remain to show high returns (de Mel et al., 2008; de Mel et al., 2014; Fafchamps

[*3] As we surveyed the area before the study, we note several NGOs provide a relief credit to flood victims, but not regular finance. In selecting the study site, we purposefully chose the population without access to any financial institution.[Abu-san: A better description for this?]

[*4] Our study matches the scale of lower equilibrium of Lybbert et al. (2004) which is much smaller than the scale of the high equilibrium of around 50 herd size.

et al., 2014; Bandiera et al., 2017). [*5] Lack of mean impacts led researchers to look for a particular subgroup which shows impacts, or impact heterogeneity (Banerjee et al., 2017): Borrowers with prior experiences or high ability are shown to have higher returns (Banerjee et al., 2015c; McKenzie, 2017; Buera et al., 2017; Banerjee et al., 2019). The studies with a focus on experienced members or existing firms can be considered as looking at impacts on the intensive margins. In contrast, our study is focused on an isolated greenfield population, or poverty impacts on the extensive margins, which are relatively less studied.

The fact that experienced members gain larger benefits from microcredit is consistent with the positive impacts of capital grant programs on existing firm owners. Whether such experience is trainable for novice entrepreneurs remains unsettled. A recent microfinance study indicates that there is an advantageous selection through talents in the existing firm owners, so trainability is called into a question (Banerjee et al., 2019). A growing body of management capital literature in developing countries is insightful yet most of the research is necessarily geared to existing firms, so it does not inform much on how one can assist novice entrepreneurs.[*6] Karlan and Valdivia (2011); Bruhn and Zia (2011); Argent et al. (2014) are the exceptions, but results and quality of evidence are mixed and inconclusive. The current study explicitly tests if the entrepreneurship matters in microfinance by using a heifer lending with a manegerial support program. We also examine the self-selection on entrepreneurship into microcredit, which we find to exist.

The corporate finance devotes a substantial part of its field in understanding the consequences of contract designs on entrepreneur's incentives. Field et al. (2013) was the first to examine if the traditional lending style of microfinance inhibits the spawning of entrepreneurship by experimentally allocating different types of debt contracts. As we will disscuss in the Section V, our study follows the similar strategy. In an attempt to tease out the impacts of entrepreneurship, we introduced longer maturity and a grace period in other arms. While there was a strong concern among practitioners that frontloading with a grace period induces untruthful borrowing, there was no alternative in borrowing other than relatives and money lenders due to ruralness and isolation. This gave us flexibility in designing the debt contracts. Similar to Beaman et al. (2015) who redesigned the repayment schedule in adapting to the borrower's cash flow profile (repay after harvest), we designed the debt contract to best suit the cash flow profile of the most popular investment project in the area, rearing a heifer. Our study exemplifies the economic gains from designing the debt contract to match the presumed investment choices in microfinance.

Another strand of the literature related to our study links capital grant effectiveness with the production set nonconvexity. Theories base lumpiness and credit market imperfection as keys to a povety trap (e.g., Galor and Zeira, 1993). When the production set is convex, a small scale transfer may not lead to a sustained increase in income, as it can be either consumed or invested to a technology with decreasing marginal returns that brings back to the original income level (i.e., the lower equilibrium of a poverty trap).

Despite its popularity as a theory, the empirical evidence of a poverty trap is mixed. Kraay and McKenzie (2014) note that a poverty trap finding is rare, while Barrett et al. (2016) state the otherwise and there is overwhelming evidence.[*7] Interestingly, however, they both agree that, when there

[*5] This is due partly to insufficient statistical power (McKenzie and Woodruff, 2013). Banerjee et al. (2015a) collects five studies of microfinance lending impacts. They also point the lack of statistical power due to low take up while noting more able and experienced borrowers saw larger "transformative effects." In the current study, in contrast, the take up rate is relatively high at 74.32%, of which 5.16% is lost to the flood.

[*6] Bruhn et al. (2018) shows intensive management consulting services to the small scale firms in Mexico resulted in sustained improvements in management practices which led to higher TFP and larger employment. Others also show effectiveness (Calderon et al., 2011; Berge et al., 2012; Bloom et al., 2013) while others do not (Bruhn et al., 2012; Karlan et al., 2015). McKenzie and Woodruff (2013) put them as: These managerial impacts studies are too different to compare, in terms of population, interventions, measurement (variables, timing), and most importantly, implied statistical power in the design.

[*7] Kraay and McKenzie (2014) also note that upward transition from one poverty trap to another may negate the notion

is a range of assets and production opportunities, it is inherently difficult to emipirically single out a particular poverty trap, and that existing evidence comes mostly from remote and isolated areas with a single primary production opportunity and an associated asset. Our study is no exception. It comes from a remote and isolated area of the Northern Bangladesh where the single most important production opportunity is cattle rearing.

An earlier finding of a poverty trap includes the cattle herd size dynamics of Southern Ethiopian pastoralists that indicates existence of a poverty trap over a 17 year recall period (Lybbert et al., 2004). More recently, Balboni et al. (2020) estimates the equation of motion for assets and show the direct evidence of a poverty trap among the recipients of a large scale transfer program targeted in the neighbouring areas of our study site. The source of nonconvexity is cattle and the complimentary assets (vehicles) at the baseline which serve as a fixed input that the ultra poor cannot afford. Similar to these studies, our study examines the nonconvexity of a higher-return production set. Our study regresses the future asset values on the current asset values and intervention dummies, thereby adding evidence, in the Barrett et al. (2016)'s terminology, using the direct method. By complementing this result with the fact that borrowers purchase cattle only when large upfront liquidity is provided, we conclude that there is a poverty trap. In our study, the source of nonconvexity is the price of a heifer that is about three times more than a goat and is not readily affordable to many residents. We also show that frontloading the liquidity in lending is effective in escaping the poverty trap.

Lastly, selecting the ultra poor as the population to provide supports have often involved free consultation/training and transfers in the past. A few studies of ultra poor transfer programs report sustained increase in assets and incomes (Blattman et al., 2014; Banerjee et al., 2015b; Blattman et al., 2016; Haushofer and Shapiro, 2016). A transfer program in the Northern Bangladesh shows an occupational change and an income increase (Bandiera et al., 2017) and long-run asset accumulation (Balboni et al., 2020). In an attempt to test commecial viability, our experimental design makes a reference to markets. It uses loans rather than transfers, and any training and consulting components charge a fee for services. The resulting repayment rates are not lower than the majority of representative microfinance programs, and we also find significant accumulation of assets. Our study can be considered as an example of market based interventions that can play a role in ultra poor programs.

III Background

The study area is in the river island, known as *chars* in Bengali, of northern Bangladesh in Gaibandha and Kurigram districts. Chars are formed by sediments and silt depositions and are prone to cyclical river erosions and floods. Chars are not stable in size and even in existence, and episodes of their partial or complete erosion or submerging are quite common. Chars accommodate ultra-poor inhabitants who are forced, as a desperate attempt for survival, to relocate across islands due to river erosion and floods.

In the study area, the asset, a heifer, is the prime investment choice. A heifer needs to be at least two years old to start lactation.[*8] Rearing costs are higher for cattle as it requires fodder while a goat will eat the bushes. Cattle requires vaccination shots when a goat is usually left unvaccinated. Reproductive capacity of goats are high.[*9] However, in comparison with cattle, their higher repro-

of a trap, while Barrett et al. (2016) base their affirmation by counting both the direct asset dynamics and the indirect inference that tests the behavioral responses that are consistent with poverty traps. See also Carter and Barrett (2006); Barrett and Carter (2013) for earlier evidence and discussions.

[*8] They typically need to be about 15 months old to be ready for insemination and takes about 9.5 months to deliver a calf as it starts lactation, or the total of about 2 years.

[*9] Parity size approaches to 2 at the third birth, and the birth interval is about 200 days (Hasan et al., 2014). An indigenous cow has a birth interval of 375 to 458 days (Hasan et al., 2018), resulting in about 2 years for gestation and calving interval (Habib et al., 2012) with the mean lifetime births of 4 (Hasan et al., 2018, Table 1).

ductive capacity and lower rearing costs are more than offset by the elevated morbidity and mortality risks,[*10] and a less frequent cash flow.[*11] In comparison with smaller livestock such as goats, cattle is more versatile in flood-prone areas. Residents also report that a goat herd is less mobile than single cattle when they are forced to evacuate during the flood. All of these considerations prompt residents to opt for cattle when they can afford it, and do not expand the herd size of goats, which are both confirmed in our data.

IV Study sample

Our sample is drawn from the population of river island villages in Northern Bangladesh. [Can someone provide the regional characteristics of the area, esp. poverty, using statistical information?]

In the *char* region, the majority of *char*s have only one village. The majority of *char*s have no MFI activity, and we delisted the *char*s if any of MFI, NGO, or *Char Livelihood Program (CLP)* is active. Using a Landsat imagery, we identified 128 *char*s within a day boat ride from the Gaibandha peer and collected information by field visits. From this list of *char*s, we randomly selected 80 *char*s. In each village, we formed a member committee of 10 households, of which 6 are ultra poor and 4 are moderately poor. The poverty status was determined by a participatory ranking process. Following a process similar to the paired ranking as in Alatas et al. (2012, p.1212) and the Peruvian ultra poor case of Karlan and Thuysbaert (2019, p.66), we asked the least wealthy households in terms of asset ownership.

After receiving acceptance for study participation ('pre-acceptance' in Figure 1), baseline data was collected in 2012 prior to the debt contract type randomisation. After offering the each type of debt contract, three groups opted out as a group. In addition to group level rejection, we had 89 individual loan rejectors. This happened despite we had explained about the debt contract types, the random assignment process, and had obtained everyone's consent to participate before randomisation. Although both type of rejecters refused to receive a loan, they gave a consent to be surveyed so we tracked them in subsequent survey rounds.

While loan rejecters remained in our sample, we lost four groups to floods in 2013. As they relocated, we had no choice but to drop them from the study. In our study, attrition refers to a household drop out from our survey. Rejection refers to a loan rejection in our intervention, and majority of rejecters (81.25%) did not attrit from our household survey. Counting all other individual attriters, we have a total of 116 subjects (14.9%) who attrited by the final round.

As a result, in the baseline survey sample, there are flood victims whom we do not track, group rejectors, individual rejectors and borrowers that we track. See Takahashi et al. (2017) for more details on the randomisation and acceptance process. As we track all — barring the flood victims whose villages were washed away and other attriters — the potential borrowers including who eventually opted out the borrowing, we are able to estimate the intention-to-treat effects of offering loans with different feartures.

[*10] Indeed, morbidity of goat kids ranges from 12% (Mahmud et al., 2015) to more than 50% in some diseases (Nandi et al., 2011, Table 5), while cattle morbidity is around 22% (Bangar et al., 2013). Goat kid mortality ranges from 6% (Mahmud et al., 2015) to 30% (Paul et al., 2014, Table 5) (Ershaduzzaman et al., 2007). Heifer mortality is between 5% (Hossain et al., 2014, p.332R) to 10% (Alauddin et al., 2018). Higher morbidity of goat kids partly reflects their eating style that uses lips rather than tongues (as cattles do) and vulnerability to logging water.

[*11] Produce of goats are mostly meat. Cow's lactation length is 227 days and milk yield is 2.2 kg per day (Rokonuzzaman et al., 2009) while goat milk is seldom marketed. A meat market requires a cluster of relatively high income earners, which takes some efforts to get to from the river islands. Goat meat sales is seasonal and it does not provide a frequent cash flow.

Source: Estimated with GUK administrative and survey data at the baseline. Survey respondents include nonparticipants to the experiments.

Notes: 1. Information of original 800 households. Values are means, values in brackets are standard deviations.

2 HeadLiteracy, HeadAge are literacy and ages of household heads. HHsize is total number of household members. FloodInRd1 is flood exposure at baseline. NumCows is cattle holding per household. NetValue is net asset values per housheold. Attrited indicates attrition rates in the household survey, and GRejected and IRejected show group rejection rates and individual rejection rates to the lending program. Active indicates the nonattrited borrower ratios. Because attrition and rejection are separate events, a household can reject and attrit, so active members ⩾ total - (rejected members + attrited members).

Table 1 shows descriptive statistics of sample households. As we randomly allocate them into four different arms, traditional, large, large grace, and cattle, summary is shown by the arms. As shown in the Appendix, these baseline household characteristics does not differ statistically between the arms. Our sample is characteretised by relatively low literacy rate (HeadLiteracy) and relatively young age (HeadAge) of the household heads. Literacy rate is lower than the national average of adult males at 61.54% in 2012 (UNESCO). Household size (HHsize) is not large, around 4.1-4.3 members, due probably to the constant flood threats, as indicated by above 40% exposure at the baseline (FloodInRd1), that do not easily allow a large household formation. Cattle holding per household (NumCows) shows cattle rearing is not common and the mean herd size is between .2 to .3. Mean net asset values per housheold (NetValue) differ between the arms, but they mostly reflect sampling errors as indicated by the large standard deviations. Attrited indicates attrition rates in the household survey, and GRejected and IRejected show group rejection rates and individual rejection rates to the lending program, which happen separately from survey attrition. We will analyse attrition and rejection later in Section VII.1, but at this point, we just note that the attrition rates are not statistically different between the arms. Active indicates the nonattrited borrower ratios. Because there are more rejecters in the traditional arm, active member ratio is smaller.

V Experimental design

To investigate the detailed demand-side constraints and suitable credit scheme for the ultra poor, we implemented the village-level clustered randomization across the four treatment arms as follows:

T1 Traditional microcredit. The design of this treatment arm is similar to that of the flagship Grameen-style microcredit lending, which is very popular in Bangladesh. Under this treatment arm, members of the group receive 5600 taka (approximately USD 50) credit, and the loan repayment begins two weeks after the disbursement. Members repay with weekly installments and are required to attend weekly meetings as well as to regularly save an amount decided jointly by the group members. The loan maturity is one year, and borrowers are allowed to take another two loan contracts of equivalent amounts over the next consecutive years. The weekly repayment is 125 taka (approximately USD 1.1) payable in 50 installments.

T2 Upfront lumpy credit without a grace period. Under this treatment arm, group members receive 16,800 taka credit with a longer loan maturity, and the loan repayments begin two weeks after the disbursement. The weekly repayment and the design of compulsory saving are exactly the same as in T1 arm. The loan maturity is three years. The required weekly repayment is 125 taka payable in 150 weekly instalments (for three years).

T3 Upfront lumpy credit with a grace period. Under this treatment arm, group members receive 16,800 taka credit with loan repayments begin one year after the disbursement. During the first year grace period, members are required to meet weekly and follow group activities such as compulsory savings just as in other arms. The design of compulsory saving is the same as in the T1, T2 arms. The loan maturity is three years. The required weekly repayment is 190 taka (approximately USD 1.7) payable in 100 weekly installments, starting after one year.

T4 In-kind credit with a one-year grace period and managerial support programs.[*12] Under this treatment arm, group members receive in-kind credit in the form of a one-year old heifer with the price of 16,000 taka (approximately USD 145), and the loan repayment begin one year after the disbursement. The grace period length is equal to the one provided under T3 and T4 arms. As stated in footnote *8 in Section III and given that we acquire one year old heifers, a one year grace period results in two year old heifers, which is the age they start lactation. In addition, the members receive fodder, training on cow rearing, regular veterinary and vaccination services, and marketing consultancy services from the local NGO, at the total fee of 800 taka (approximately USD 7.2) charged over the three years.

One of the aims of the study is to assess if the entrepreneurship matters in microfinance lending outcomes. Assuming that, below 17000 Taka, the productive asset with the highest return is a heifer, we bundle training and consultation with a heifer lending. At the start of a loan, our expert procures a heifer from the local market, so the borrower does not have to have the knowledge required for the quality purchase. We provide knowledge to a group of borrowers through training and disallow an investment choice by leasing out an asset, so a part of entrepreneurship will no longer be a prerequisite. It can be seen that we are offering a capacity to use the best practice or the *cristalised intelligence* related to cattle production (Cattell, 1963). This is only a part of entrepreneurial skills. The remainder, a capacity to apply a suitable action to unforeseen events or the *fluid intelligence* related to cattle production, and other inter-personal skills, are left unchanged. If the entrepreneurship raises productivity, borrowers of other arms who are not provided the knowledge are expected to opt out the loan or perform worse. One can measure impacts of the entrepreneurship by comparing these two groups, in-kind credit with training vs. cash credit.

As a natural reference, we want to compare the training cum in-kind loan T4 with the traditional regular microcredit T1, a classic Grameen style loan that is about a third in loan size and maturity with no grace period. In order to make comparison feasible, we added two intermediate treatment arms to bridge them: Two arms with upfront lumpy lending that is equivalent of a heifer price, one with a grace period T3 and another without a grace period T2. With the loan sizes that are three times

[*12] It is almost the same as the finance lease, but it is difficult to distinguish it from a debt with the purchased asset set as a collateral. Under a finance lease, asset ownership belongs to the lessor, while under a collateralised debt, the asset ownership moves to the borrower. Heifer ownership was never explicitly agreed upon, and it is generally understood by the borrowers that they own the heifer, which gives similarity to a collateralised debt.

Note: Cell contents are hypothesised constraints on investments that exists in the column arm but are eased in the row arm. Contents in brackets are variable names of respective attributes.

the traditional microfinance loans, we extended the maturity to three years to even out the repayment burden. The comparison arm, the traditional regular microcredit, has only one year maturity.[*13] We therefore provided the total of three loans in three loan cycles in T1 which are unconditionally disbursed annually, so the total loaned amount will be aligned and there is no exit-selection due to delinquency before three cycles are complete.

Under this setting, frontloading liquidity without changing the total loan size eases a liquidity constraint, attaching a grace period under the same loan size and disbursement timing eases a saving constraint prior to a loan receipt, and offering an in-kind loan with a managerial support without changing other features eases an entrepreneurship constraint. In effect, we constructed a stepped-wedge design over these key features of loans, namely, upfront liquidity (Upfront), a grace period (WithGrace), and in-kind with managerial supports (InKind), to assess the impacts of respective constraints on participation and outcomes as indicated in TABLE 2.

An in-kind offer in treatment T4 is generally thought to be less efficient than a cash offer as it takes away an investment choice from the borrower. However, the local microfinance practitioners widely agree that other production opportunities are limited, so not much is lost in terms of the choice set, under our setting of island location and occasional floods.[*14] Given the small set of the productive investment choices, our experiment gives a unique chance to compare cash lending against in-kind lending, even without controlling for a potentially wider choice set of cash lending. Indeed, we found in our data that most of cash borrowers started to invest in cattle after receiving a loan. Consequently, in our study, the cash-grace-period and in-kind-grace-period lending differ effectively only in the managerial support services bundled in the latter.

All loan products are of individual liability and the committee was intended to serve as an activity platform for microfinance operations. Among the traditional members, there were 24 members who received disbursements twice, not three times. We drop them from the analysis and use 776 members in the below. [Abu-san: Do you know why these 24 households received the loans twice, not three times?]

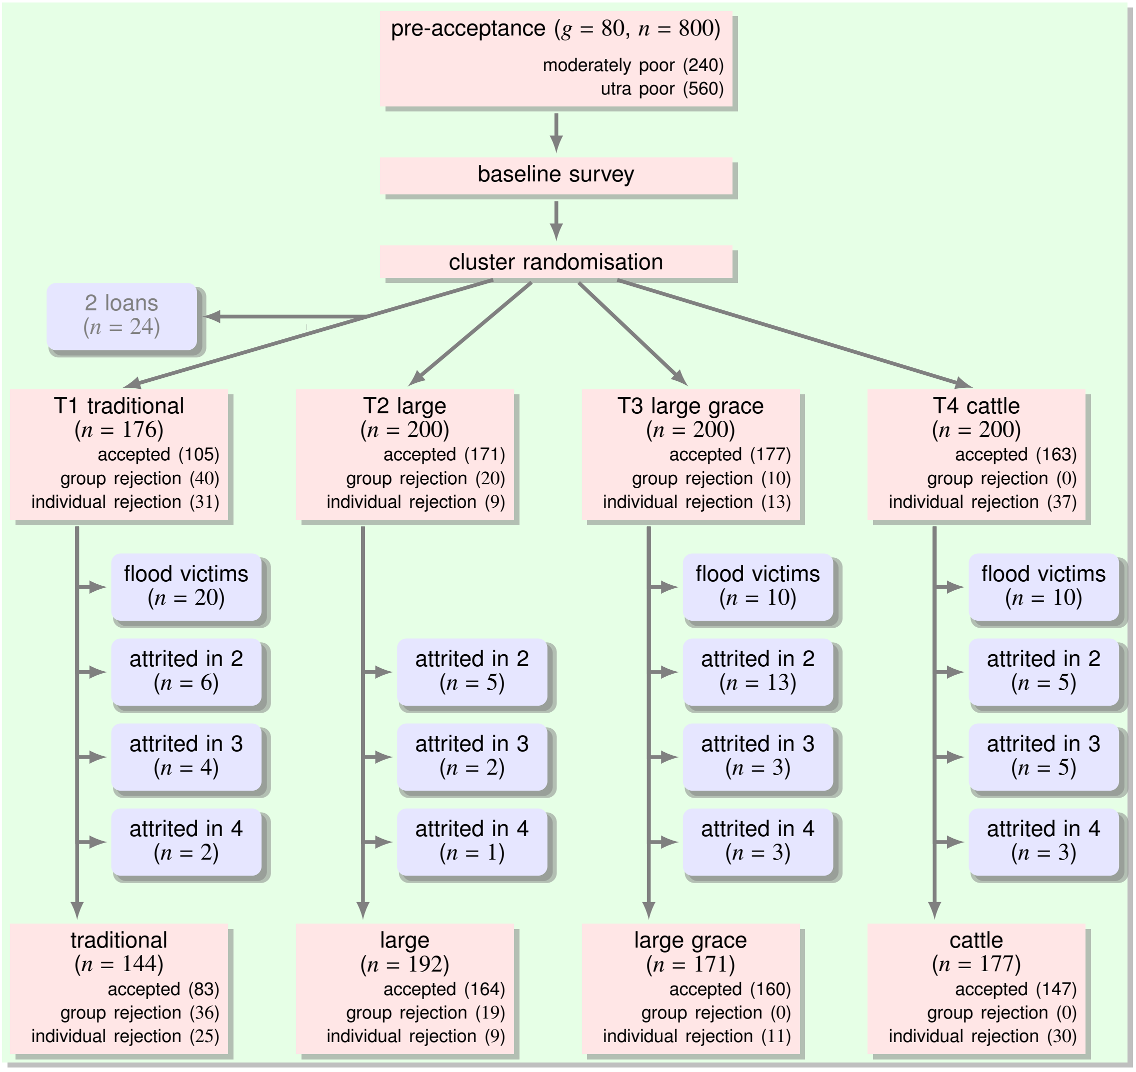
VI Empirical strategy

We collected data at one baseline survey and three annual follow up surveys. With successful randomisation (see Section VII.1 and Appendix B), we use ANCOVA estimators to measure impacts of each experimental arms and loan attributes. ANCOVA estimators are more efficient than DID estimators (Frison and Pocock, 1992; McKenzie, 2012). As we include loan rejecters, what we

[*13] Each arms have pure control groups who did not receive a loan until 1, 2 years later into the program. Due to a concern for within group spill overs, we do not use them here.

[*14] A closely related project in the neighbouring areas transfers an asset in the form of a cow (Bandiera et al., 2017).

Figure 1: Sampling framework, rejection, and attrition



are estimating is intention-to-treat effects. For an ease of interpretation, we sometimes use indicator variables of each attributes, Upfront, WithGrace, InKind in place of arms in several estimating equations. Numerically, both are equivalent. In what follows, we will refer to these attributes as *functional attributes*.

The basic estimating equation for our intention-to-treat effects is:

$$y_{it} = b_{10} + \boldsymbol{b}_1'\mathbf{d}_i + b_2 y_{i0} + e_{it}, \tag{1}$$

where, for member i in period t, y_{it} is an outcome measure, $\mathbf{d}_i$ is a vector of indicator variables in arms or functional attributes that i receives, e_{it} is an error term. For the traditional arm, the conditional mean of outcome given covariates and baseline outcome variable is given by b_{10}. For an arm or a functional attribute a, the impact relative to the traditional arm is measured with b_{1a}. As we are interested in the time course of impacts, we allow for time-varying impacts as:

$$y_{it} = b_{10} + \boldsymbol{b}_1'\mathbf{d}_i + b_{t0}c_t + \boldsymbol{b}_t' c_t \mathbf{d}_i + b_2 y_{i0} + e_{it}, \tag{2}$$

where c_t is a period indicator variable for $t > 1$ that takes the value of 1 at t, 0 otherwise. We use the second period (period 2 in most cases) as the reference for time dummies. b_{t0} measures the period t deviation from b_{10} for the traditional arm, $\boldsymbol{b}_t'$ measures the period t deviation from the concurrent traditional arm for non-traditional arms or functional attributes. For the traditional arm, the conditional mean of outcome given covariates and baseline outcome variable is provided by $b_{10} + b_{t0}$. For the non-traditional arms, the deviation of conditional mean, given covariates and the baseline outcome variable, from traditional arm outcome in period t is provided by $\boldsymbol{b}_1 + \boldsymbol{b}_t$ with $\boldsymbol{b}_t = \mathbf{0}$ for $t = 2$. Cumulative impacts are time-series sums of each impacts. In the Section VII, we will plot and focus on the cumulative conditional mean deviations of each non-traditional arms in each period. All the standard errors are clustered at the group (char) level as suggested by Abadie et al. (2017).

VII Results

The reasons behind nonparticipation are fundamental in understanding the outreach. We analyse nonparticipation in relation to the debt contract design that they were randomly allocated to. In addition, selective attrition from the household surveys, if any, biases the estimates so we need to compare the attriter's characteristics with the nonattriters. In this section, we check how participation and attrition are different between the arms by using permutation tests. We use the coin package of R with 100000 random draws from all admissible permutations.

VII.1 Participation

As noted in Section V, there are two kinds of rejecters to participation. One is group rejecters who jointly turned down the offer as a group, and another is individual rejecters who decided not to participate while fellow members of the group participated.

Group rejecters of traditional and non-traditional arms differ in household characteristics. In the Appendix C, it is shown that the asset-poor households did not participate in the traditional arm, while it is recent flood victims who did not participate in the non-traditional arms. Given randomisation, we conjecture that it is lack of Upfront liquidity that prevented asset-poor households of traditional arm from participating because they cannot purchase cattle due to insufficient net asset values or an insufficient resale value of owned livestock, when members of similar characteristics partcipated in non-traditional arms.

Individual rejecters of traditional arm and non-traditional arms share similar characteristics (Table 3).The common factors associated with nonparticipation are a smaller household size and smaller livestock holding, although the p values for livestock holding difference between individual rejecters and non individual rejecters are around 7% .

These hint that it may take a larger household size to raise cattle. It is possible that smaller households may be facing a domestic labour constraint or a space limitation to accommodate cattle under the roof. These constraints are expected to be absent in asset transfer programs where targeted residents can sell the asset if either of constraints binds. We conjecture that the households under a binding liquidity constraint and/or a binding domestic capacity constraint did not meet the conditions to raise cattle, and have withheld themselves from the program with individual rejection. This self-selection may have caused the repayment rates to be higher than when everyone participated.

A strong correlation between baseline flood exposure and individual rejection among the non-traditional arm members suggests that a population prone to natural calamity and associated asset shocks have voluntarily opted out the borrowing. This partly explains the lack of commercial and even noncommercial/NGO lenders in the flood prone area.

It is worth noting that partcipants of cattle arm differ from other arms in having less cattle rearing experience as observed in smaller initial cattle holding (p value = .156) and in having lower asset values (p value = .058, Table 4). These features that are plausibly disadvantageous in rearing a heifer notwithstanding, the cattle arm with training induced partcipation. As we will see in Section VII.3, the choice of lending vehicle (cash or in-kind) does not matter in investments. So it is natural to infer that the training component has induced the members with less experiences and fewer assets to take

TABLE 3: INDIVIDUAL REJECTERS VS. NON-REJECTERS

n	105	31	(rate 0.228)	511	59	(rate 0.104)	616	90	(rate 0.127)

Note: Individual rejecters are the members who did not accept a loan based on an individual decision after the period when group rejection was decided. After 70 people group-rejected, the total number of individuals who was in a position to individually reject the loan was 706 people, of which 90 individually-rejected. Non-traditional arms are large, large grace and cattle arms. The variable Arm is the ratio of traditional arm members in individual nonrejecters and individual rejecters.

TABLE 4: CONTRASTING CATTLE ARM AND OTHER ARMS, BORROWERS AND NON-ATTRITING BORROWERS

	borrowers			non-attriting borrowers		
variables	Cattle arm	Other arms	p value	Cattle arm	Other arms	p value

n	163	453	(rate 0.265)	147	407	(rate 0.265)

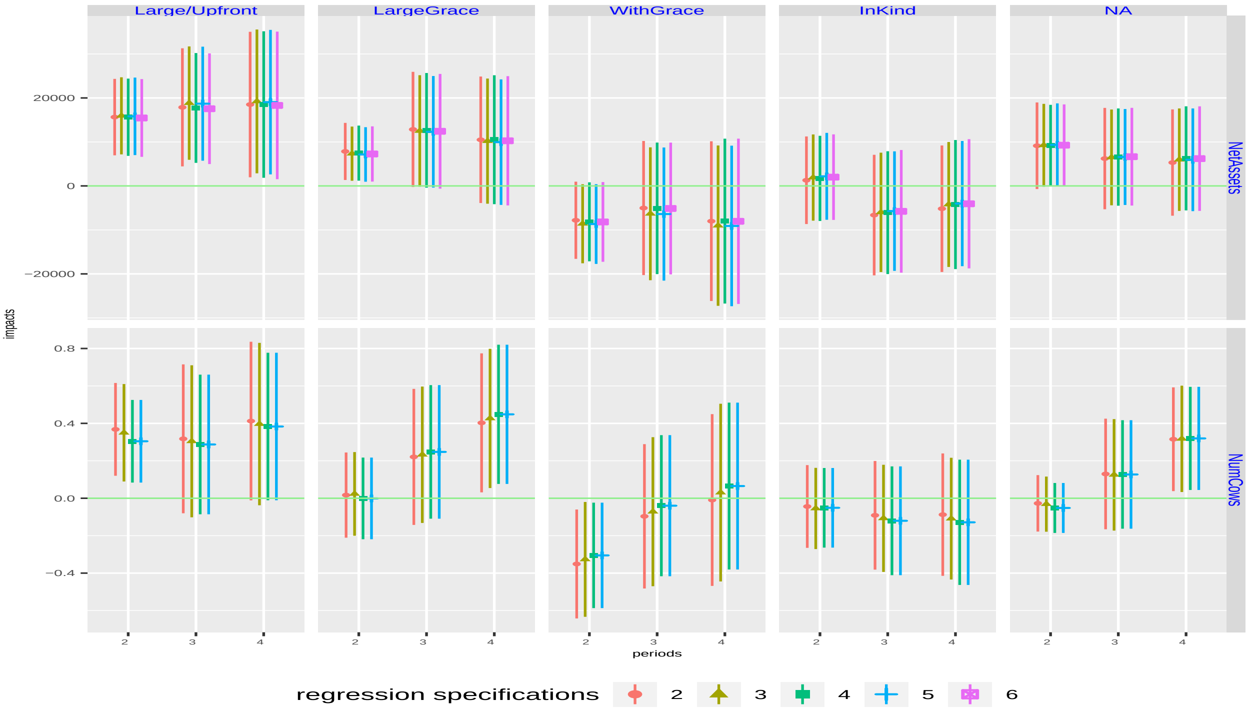
Note: Borrowers are members who accepted a loan, non-attriting borrowers are borrowers who stayed in the survey until the final round. Both borrower panel and non-attriting borrower panel show the contrasts between the cattle arm and all other arms. Borrower panel compares the difference in participant characteristics between cattle and other arms. Non-attriting borrower panel compares the difference in non-attriting participant characteristics between cattle and other arms. Both show cattle arm induced participation of asset-poor households at the beginning and until the end of the project.

up loans. In addition to participation, cattle arm members who survived (defined as participation and non-attrition) by the end of final survey rounds have smaller baseline livestock holding (p value = .016) and baseline net asset holding (p value = .007) than other arm's members . These hint that more disadvantaged borrowers participated and managed to survive until the end of the study in the cattle arm with a help of managerial supports.

VII.2 Attrition

The survey resulted in the attrition of a moderate rate, 14.9%. We checked for systematic differences between attriters and nonattriters and found the attrition is not correlated with any household level characteristics (see more detailed attrition examination in Appendix D). We also found that traditional arm attriters have a lower rate of head literacy while non-traditional arm attriters are more exposed to the flood and have a larger household size. One can argue that, with attrition, the estimated impacts of borrowing could have increased for the traditional arm and have not increased for the non-traditional arms. Such a conjecture hints there may be underestimation, if any, but it is unlikely to inflate the impact estimates.

Figure 2: Cumulative effects on livestock and net assets



Source: Constructed from ANCOVA estimation results.

Note: Left most column panel shows the conditional means of traditional arm which serves as a benchmark in estimating impacts. In other column panels, all points show the relative difference from concurrent traditional levels depicted in the left most column. Large and Upfront are the same values. Other column panels are grouped either by arm or by attribute. Row panels show different outcomes. Bars show 95% confidence intervals using cluster robust standard errors.

VII.3 Impacts

Figure 2 summarises the cumulative impact estimates in time-varying specification of (2). See Appendix E for full estimation results. There are two stock outcome variables, number of cattle and net asset values, where net assets are defined as total assets less debt outstanding to all sources. For each outcome, there are five panels of arms and functional attributes. Since large arm and Upfront functional attribute are numerically same in (2), they are put in one panel column. In all panels, points show the estimates of cumulative deviation from concurrent traditional arm values, or how much the impacts relative to traditional arm have evolved. Vertical bars indicate 95% confidence intervals. For all panels, in each period, there are several estimation specifications bunched side-by-side. [*15] This is intended to show robustness to specification changes at a glance.[*16] One sees that there is little variation across specifications.

There are notable tendencies in the figure. First, in both cattle holding and net asset panels, point estimates show there is a one time increase at period 2 in the Large/Upfront column. The non-traditional arms have increased cattle holding and net assets once and stayed increased relative to the traditional arm. As time passes, standard errors get necessarily magnified because borrowers get exposed to more random variations, so the bars grow longer and p values get larger, making the

[*15] Specification 1 is omitted from the plot, because it is an OLS regression without the baseline outcome that is intended to provide a reference for ANCOVA estimates.

[*16] As multiple specifications are estimated to show uniformity of results, not to pick one specific estimate, inference corrections for multiple testing are unncessary.

estimates noisier and error bars crossing the zero line in round 4.

Secondly, it is the Upfront functional attribute that shows positive impacts in both outcomes. This is consistent with the nonconvex production technology of a larger investment under a liquidity constraint, coupled with an inferior, smaller investment technology.

Thirdly, comparing the impacts of the InKind attribute on both stock outcomes against Upfront and WithGrace, we see statistically zero differences. In light of the fact that individuals with less cattle rearing experiences and lower asset values participated and survived in the cattle arm, the finding that their outcomes are statistically indistinguishable from other non-traditional arms implies the treatment arm facilitated the returns to cattle rearing at no lower level. The managerial supports of cattle arm have induced participation and achieved the same level of impacts among the members who would otherwise not take a loan, probably out of their relatively disadvantaged background characteristics. The reason can either the managerial support program complimented the necessary codifiable knowledge, or these participants had the same level of knowledge as other participants but found the utility of the managerial support program. Either possibility is consisitent with the finding by previous studies that only the experienced or skilled members could reap the benefits of microfinance. Previous studies have targeted the population with a richer set of investment possibilities in a more urbanised setting under which the experience may have a positive return. In the current study, the population resides in a remote, rural area. Even the simpler production process of dairy cattle farming that consists of procuring feeding, grazing, insemination and calving turns out to demand unignorable codifiable skills, or the crystalised intelligence, to participate and sustain in microfinance.

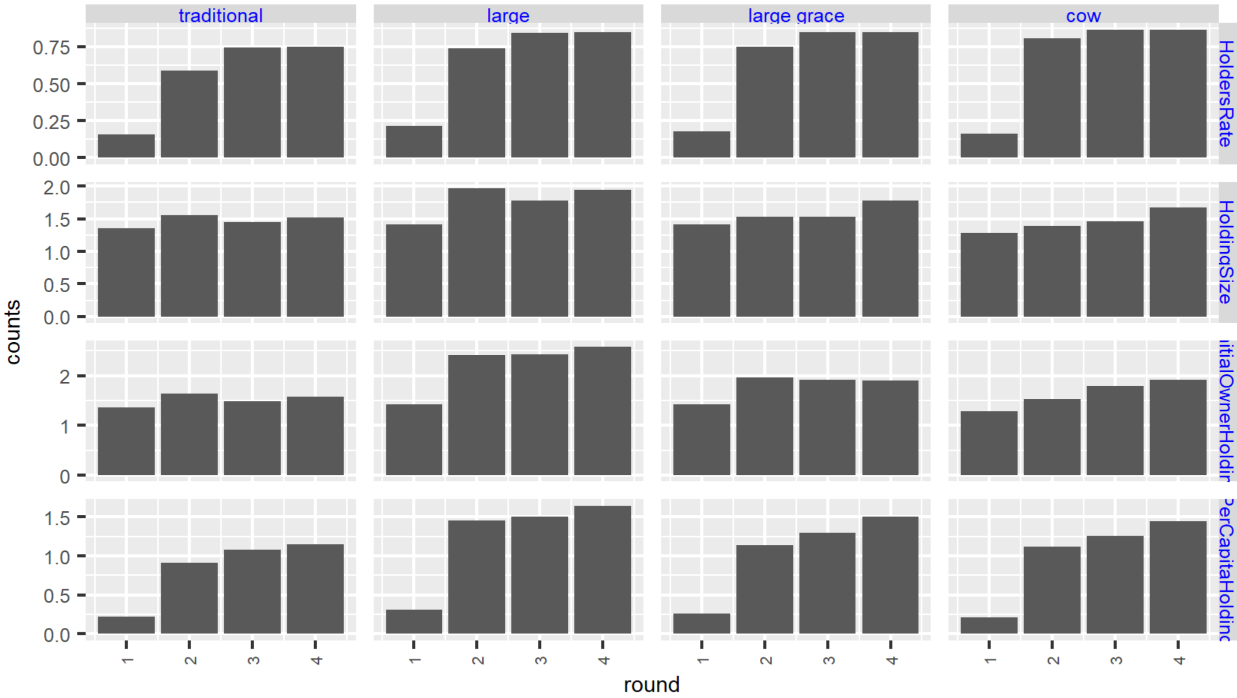
The NumCows row shows the number of cattle owned and it also serves as a check that non-traditional members actually own cattle once the loan/lease is made. The ANCOVA estimates plotted in the figure are net of baseline cattle holding, so even the non-traditional holding estimates sometimes add up to less than 1. The figure shows that, on average, the non-traditional arms continue to own about .5 more cattle than the traditional arm members, conditional on the initial cattle holding.

Figure 3 shows more detailed changes in cattle ownership by arm. Holder rates are the number of cattle owners per arm size, holding size is average holding per owner, initial owner holding are herd size for owners who held cattle at baseline, and per capita holding is mean cattle holding in each arm. Initial owner holding and holder rates show impacts on the intensive and extensive margins, respectively. Per capita holding tracks impacts on both the intensive margins (growth of initial owners) and the extensive margins (growth of new owners). All the indicators are similar across arms at the baseline.

We see that the holder rates increased in all arms, but the increase was smallest for the traditional. This shows that, even the small upfront lending of traditional arm helped increase catte ownership but to a lesser degree. Without equally large upfront liquidity and the repayment installments that began immediately, a smaller fraction of borrowers could purchase their first cattle. Holding size increased in all non-traditional arms, while the traditional arm remained stagnant. It is also the traditional arm that has the smallest, or negligible, impacts on the initial owners. [These initial owners, overall, diversified their portfolio rather than increasing the cattle investments.] Initial owner holding size is larger than the average holding size per owner for the non-traditional arm, indicating the higher returns to members with experiences. The per capita holding growth was smallest in the traditional arm. This is due to smaller impacts on the extensive margins (fewer new ownership, smaller growth by new owners) and little impacts on the intensive margins (negligible growth by initial owners).

To understand the reasons behind the slower pace of asset accumulation of traditional arm, in Figure 4, we plot borrower's reported income generating activities (IGAs) separately by the total number of projects that the borrowers report. Contents of IGAs are cattle, goat/sheep, growing cereals (paddy, corn) and nuts, small trades, and house and land leasing. The row panel headed by the number '1' indicates the distribution of projects among single-project owners, '2' indicates the distribution among double-project owners, and so on. This shows that almost no one of the traditional arm invested only in one project while only few members did so in the non-traditional arms. We also

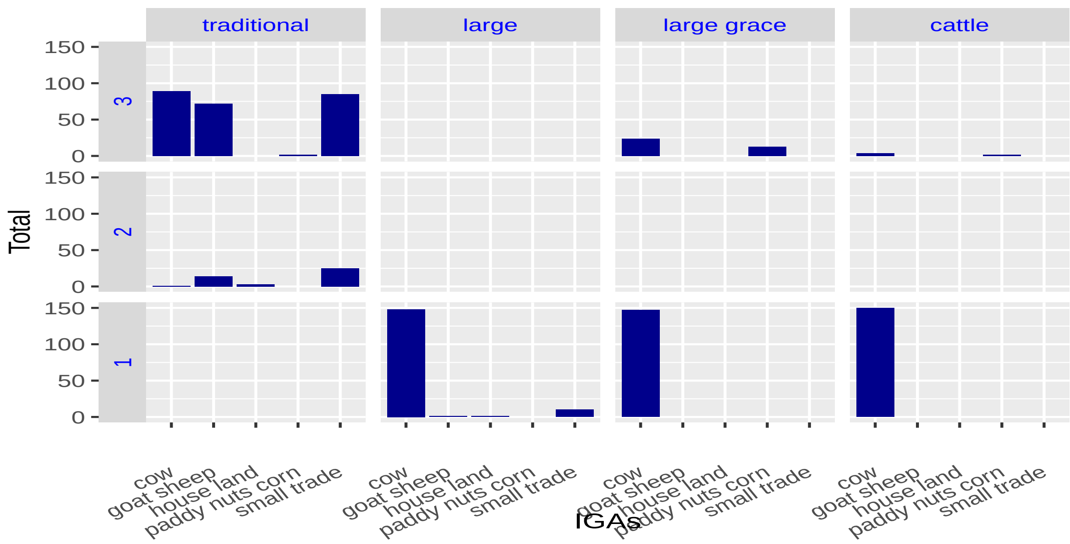
FIGURE 3: CATTLE HOLDING BY ARM



Source: Survey data.

Note: HolderRates are the number of cattle owners per arm size, HoldingSize is average holding per owner, InitialOownerHolding are average holding per owner who held cattle at baseline, and PerCapitaHolding is cattle owned per arm member. InitialOownerHolding and HolderRates show impacts on the intensive and extensive margins, respectively. PerCapitaHolding shows the time trend in mean cattle holding.

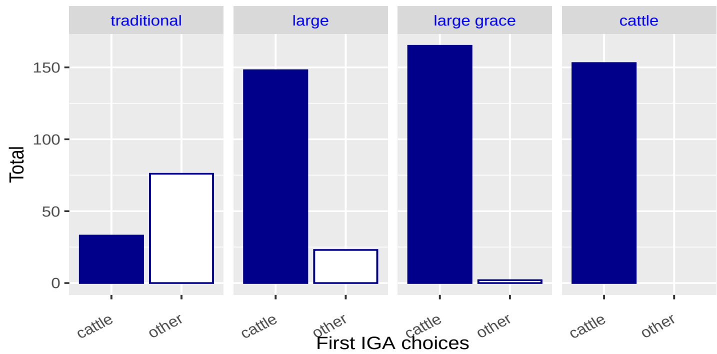
FIGURE 4: ALL IGAS



Source: Administrative data, based on the information reported at the weekly meeting. Only borrowing member data are shown.

Note: Contents of IGAs are cattle, goat/sheep, growing cereals (paddy, corn) and nuts, small trades, and house and land leasing. Row panels indicate the total number of IGAs that borrowers own. For example, the row panel under the number '1' indicates the distribution of projects owned by single project members. There is no borrower with only one project in the traditional arm.

FIGURE 5: CONTENTS OF FIRST IGA



Source: Administrative data, based on the information reported at the weekly meeting. Only borrowing member data are shown.

Note: The first IGA is defined as the oldest IGA for the household. Blue bars are the cattle rearing, white bars are the sum of all other projects listed in FIGURE 4.

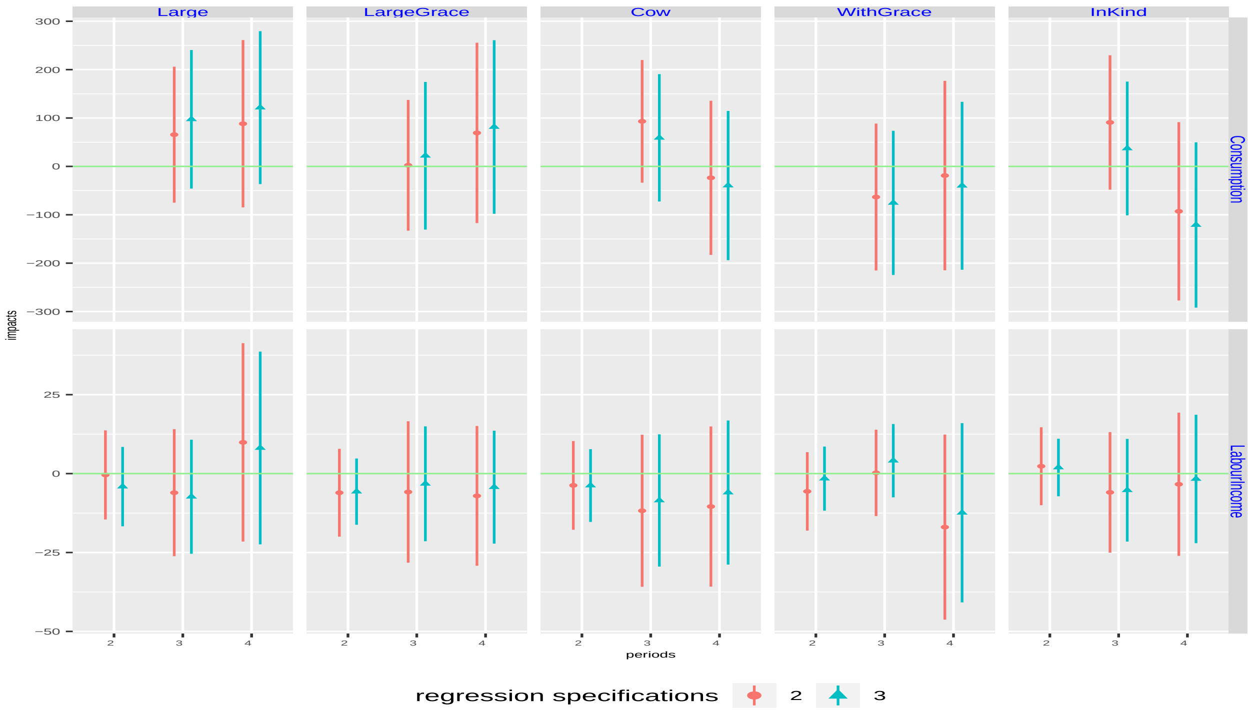
note that there are a significant number of cases in the traditional arm that members reportedly raise cattle, yet they are also accompanied by pararell projects in smaller livestock production and small trades. Popularity of small trades and smaller livestock for the traditional arm members is consistent with convexity in the production technology of large domestic animals under a liquidity constraint. This also validates our supposition in experimental design that cattle production is the most preferred and probably the only economically viable investment choice. It eases a concern that the cattle arm may have imposed an unnecessary restriction in an investment choice by forcing to receive a heifer.

FIGURE 5 shows the first IGAs of members. The first IGA is defined as the oldest IGA for the household. For most of the households, the oldest IGA had started after the baseline, and it is the IGA with the largest cash flow. Of course, there are a small percentage of households with an existing IGA before the baseline, but, with randomisation, the fraction of such households are similar across arms. Therefore, the between arm comparison of the first IGA gives us an idea about how the households had chosen the initial investments. In the traditional arm, there are 33 borrowing members who report cattle as their first IGA, and 76 borrowing members (69.72%) who report other than cattle as their first IGA. This contrasts with the non-traditional arms that 466 borrowing members who report cattle as their first IGA and 25 borrowing members (5.09%) other than cattle as their first IGA. As can be seen from FIGURE 4, for the 2nd and 3rd IGAs, a diversified IGA portfolio is continued to be held by all the traditional arm borrowers, and only the minority of non-traditional arm borrowers has a diversified portfolio.

FIGURE 6 shows impacts on consumption and labour incomes. Style and placement of panels follow the FIGURE 2. Consumption is not measured at the baseline, so we do not use it to understand the welfare impacts but to understand how the members have dealt with the loan repayment through consumption choices. Given randomisation, one can still identify impacts on repayment efforts in terms of consumption suppression relative to the traditional arm. In obtaining ANCOVA estimates, we condition on period 2 consumption. [This can be problematic as period 2 consumption is correlated with arm assignment. But the results do not change if we estimate without period 2 consumption as a covariate in specification 1.] Consumption is per capita consumption of the household. Labour incomes is a household level variable and measures earnings from day-to-day casual jobs.

There is almost no impact on consumpton in the non-traditional arms or in any functional attributes. The households seem to have put asset accumulation a priority before consumption growths. Just like the consumption, we see no impact on labour incomes in all non-traditional arms. In the Appendix TABLE E7, one notes that the labour income is highest in period 2, decreased in period 3, and increased in period 4. Former is due to the flood in period 2 when members were trying to make up for the losses with an increased labour supply. The latter rising trend is consistent with the repayment burden, and is further consistent with the view that the borrowers did not choose to strategically default but tried to repay.

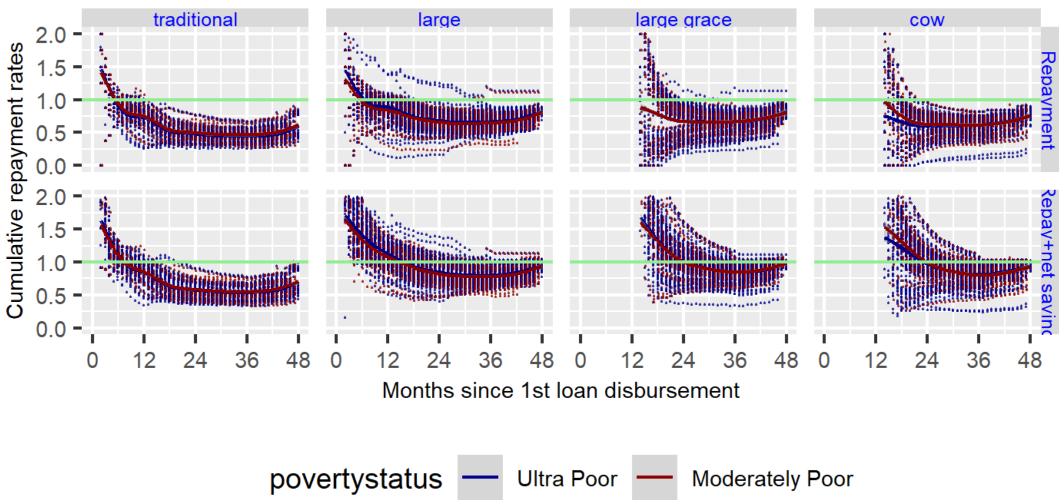
FIGURE 6: PERIOD WISE EFFECTS ON INCOME AND CONSUMPTION



Source: Constructed from ANCOVA estimation results.

Note: Left most column panel shows the conditional means of traditional arm which serves as a benchmark in estimating impacts. In other column panels, all points show the relative difference from concurrent traditional levels depicted in the left most column. Large and Upfront are the same values. Other column panels are grouped either by arm or by attribute. Row panels show different outcomes. Bars show 95% confidence intervals using cluster robust standard errors.

FIGURE 7: CUMULATIVE WEEKLY REPAYMENT RATES



Note: Each dot represents weekly observations. Only members who received loans are shown. Each panel shows ratio of cumulative repayment sum to cumulative due amount sum, ratio of sum of cumulative repayment and cumulative net saving (saving - withdrawal) sum to cumulative due amount sum, both are plotted against weeks after first disbursement. Value of 1 indicates the member is at per with repayment schedule. Horizontal lines has a Y intercept at 1. Lines are smoothed lines with a penalized cubic regression spline in ggplot2::geom_smooth function, originally from mgcv::gam with bs='cs'.

FIGURE 7 shows the repayment results. Top panel shows the ratios of cumulative repayment to cumulative planned installment, the bottom panel shows the ratios of sum of cumulative repayment and cumulative net saving (saving - withdrawal) to cumulative planned installment. Both are plotted against weeks after first disbursement. Each dot represents a member at each time point. Value of 1, which is given by a horizontal line, indicates the member is at per with repayment schedule. Some members saved more than the required repayment at each time points that go beyond 1 in the figure. One sees that repayment rates are above 1 at the beginning but stay below 1 for most of the time. The majority of borrowing members did not repay the loan by the 48th month with prespecified installments. One notes the traditional arm has more of lower repayment rates among all arms. When a member does not reach the due amount with installments, they had to repay from the (net) saving, an arrangement to which the lender and the borrowers made at the loan contract signment. Repayment rates after using net saving are 44.71, 93.57, 97.01, 95.42%, respectively, for traditional, large, large grace, cow arms and 87.85% for overall (from AllMeetingsRepaymentInitialSample.rds). [Abu-san: Why does the admin data continue up to the 48th month, not 36th?] The low repayment rates among traditional arm borrowers may be due to our experimental design that a new loan is disbursed unconditionally up to three cycles, lacking the dynamic incentives to repay.

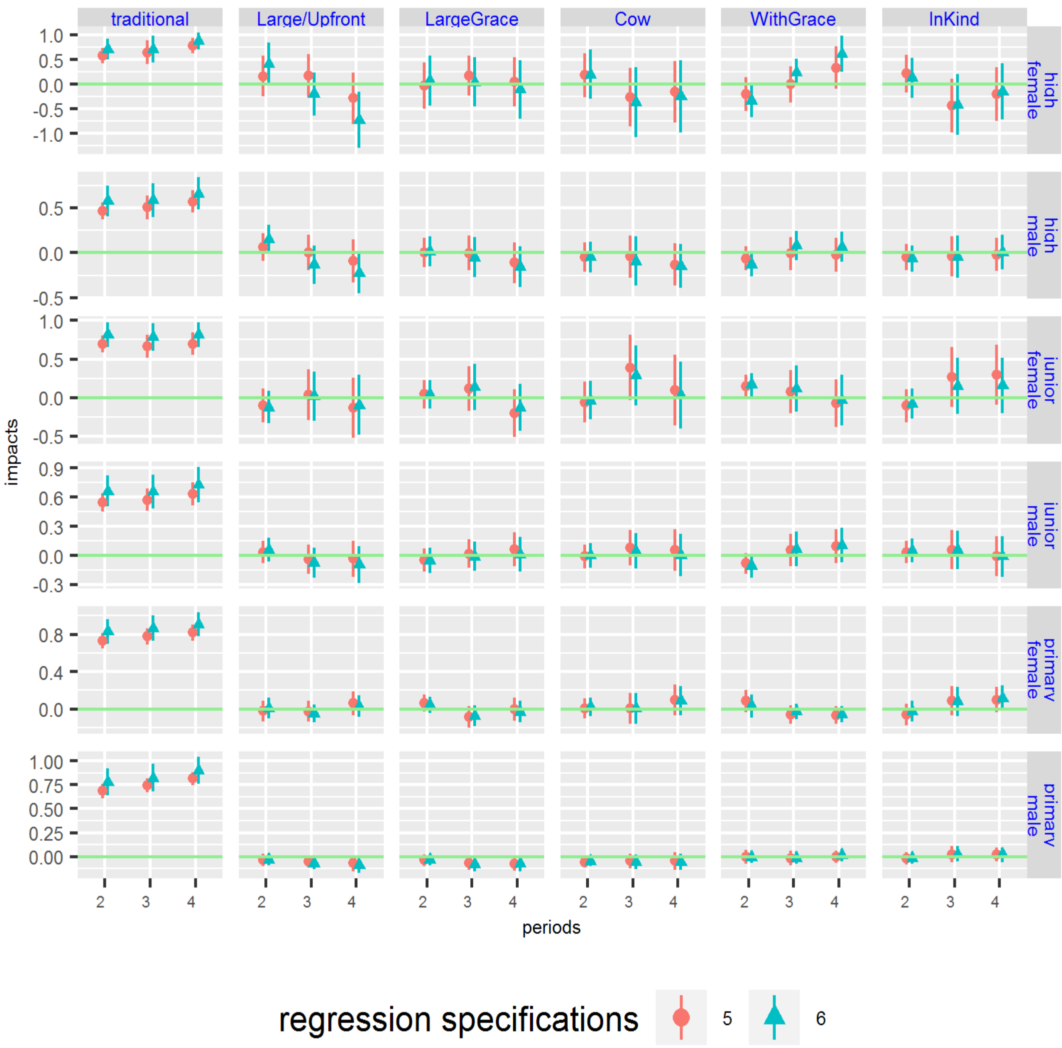
There is little difference in repayment rates by poverty classes. FIGURE 7 depicts both moderately poor and ultra poor in different colours. It is impossible to distinguish between them with eyeballs, and ANCOVA estimates also confirm this (see Appendix ?? for details). We also observe that impacts on all outcome measures are not statistically different between the poverty classes (see Appendix E). This is in contrast to a popular belief that the ultra poor are the riskiest among all income classes.

Smaller cumulative impacts and lower repayment rates of traditional arm members stand out once we acknowledge that they are receiving an equivalent amount and their contract differs with other arms only in the attributes we focus. These differences arose partly from the different investment choices observed in FIGURE 4, 5, which were induced by the different Upfront functional attribute in lending.

In FIGURE 8, effects on child school enrollment are displayed. Unlike the previous figures, traditional column shows the conditional mean values and other non-traditional columns show per period impacts relative to the concurrent traditional arm values. What we display are per period impacts, not the cumulative impacts, because annual enrollment matters in schooling while end of study values matter in assets. In general, there is no detectable impact of the intervention, except for a negative impact for women at the college level for Upfront in period 4 and a positive impact for women at the college level for WithGrace in period 4. Women at the college level are about 5.9% of sample, so the effective sample size of each cell is about 1-3, and it is difficult to interpret the results on these small samples. If anything, negative impacts of elder girl's schooling may be due to stronger demand for cattle production in a household. This is in line with the finding in rejection that the limited household size can be a constraint on participation, especially when there is no grace period. Cattle ownership naturally shifts the relative shadow prices in a household against child schooling, especially for the elder girls as their returns on human capital are considered to be lower than younger girls, and task contents of cattle rearing labour are less brawn intensive yet requires to be above the primary school ages. This may be a downside of having greater cattle production in a household.

In summary, we found that our managerial support programs induce the members of disadvantaged background to participate in microfinance, achieving the further outreach, and achieve the results that are no different with other borrowers. This is consistent with the finding of the previous studies that a certain level of skills is necessary for participation, and our managerial support progams supplemented the lack thereof. We found that the upfront loans allows borrowers to invest in cattle while members with sequential disbursements mostly opted for smaller livestock and small trades. In combination with a greater return to cattle on net asset accumulation and a greater rate of loan repayment, we consider it as evidence of a poverty trap and an effective measure to break it. We also found the impacts and repayment rates are indistinguishable between the moderately poor

Figure 8: Cumulative effects on schooling



Source: Constructed from ANCOVA estimation results.

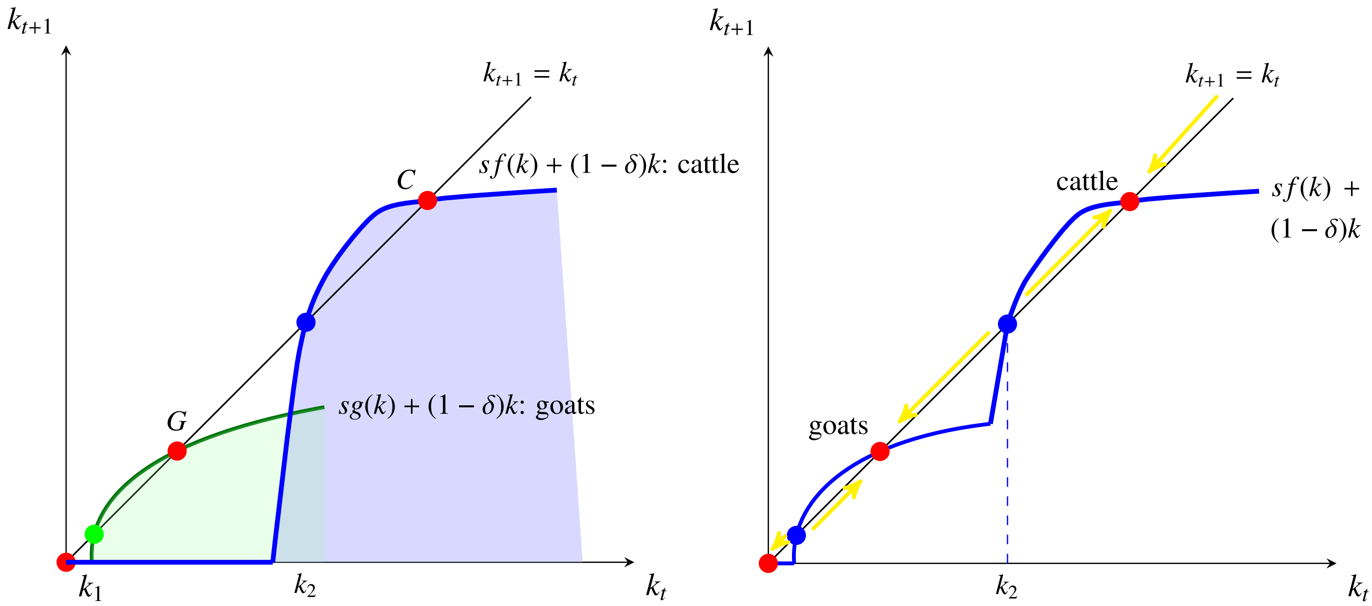
Note: See footnotes of Figure E3.

and the ultra poor.

VIII Theory

In this section, we use a simplified version of Galor and Zeira (1993) to illustrate a theoretical framework to aid the interpretation of the empirical finding that asset accumulation is faster while the repayment rate is higher for upfront lending. Let us consider that there are two production sets called 'goats' and 'cattle.' Both sets are nonconvex with fixed inputs as shown in Figure 9 (left panel), with period t per capita herd size in monetary units k_t on the horizontal axis and the period $t+1$ per capita herd size in monetary units k_{t+1} on the vertical axis. The next period net per capita herd size is given by carry over herd size net of mortality and its addition with saving. When a production set has a fixed input portion, carry over herd size is zero over that portion and becomes positive once production becomes positive after $\underline{k} \in \mathbb{R}_{++}$. This is given as the flat segment next to the origin of $sg(k_t) + (1-\delta)k_t$ for goats and $sf(k_t) + (1-\delta)k_t$ for cattle. For $k_t > \underline{k}$, taking the cattle as an example,

Figure 9: A poverty trap with goats and cattle



Note: The current period per capita herd size k_t is on the horizontal axis, the next period per capita herd size k_{t+1} is on the vertical axis. The production function for goats $g(k)$ is multiplied with a fixed saving rate s and is added current herd size net of mortality $(1-\delta)k_t$ that is passed on to the next period per capita herd size. Depreciation is zero for the fixed cost segment. Similar description applies to the cow production. The left figure shows each production sets, the right figure shows the contour of two production sets. Red points are stable equilibria, blue points are unstable equilibria.

next period net per capita herd size traces each production sets after rescaling with saving rate s with $sf(k)$ and linearly deducting the depreciation with $(1-\delta)k_t$, so nonconvex production sets are shown in the figure. We assume the population size, saving rate s, and depreciation rate δ are fixed. We note from the previous section that the returns to goats net of mortality are lower in the region depicted in Figure 9, and the steady state goat herd size is small in their livestock values. We also note that a goat investment, when comapred to a heifer investment, requires smaller upfront costs but has an infrequent income stream, faces a more limited local demand, shows vulnerability to logging water, all pointing to smaller investments. We will use these points to assume that the fixed costs and steady state production level are smaller for goats than cattle.

When there is only a goat production technology, individuals eventually reaches the point G, a steady state where the per capita herd size is constant, or $k_{t+1} = k_t$. When the cattle production technology is added to the picture, there is no change in the equlibrium for individuals whose initial assets are in $[k_1, k_2)$. For individuals with initial assets in $[k_2, \infty)$, one chooses cattle, because the resulting income level is higher, and eventually arrive at the steady state C.[*17]

Over the domain of $k_t \in [0, \infty)$, the production possibility frontier, or the contour of the union of two production sets, becomes M-shaped (right panel). Under the configuration depicted in the figure, there will be five equilibria of which three are stable. Ruling out the zero equilbrium as irrelevant, one is left with two stable equilibria, named as goats and cattle in the figure.[*18]

Formally, one requires the production set $j = \{\text{goat}, \text{cattle}\}$ to satisfy: there exists $\underline{k}_j > 0$ that the production is zero for input $k < \underline{k}_j$ and is strictly positive for $k \geqslant \underline{k}_j$. We assume the production set exhibits decreasing returns to scale for $k \geqslant \underline{k}_j$. Let the contour of the production set be $f_j(k)$. Assume for expositional simplcity that there is a fixed saving rate s. Further assume that there exists $k_2 > \underline{k}_j$

[*17] k_2 is an unstable equilibrium that no individual would deviate from, but we include this point to the region of attraction of C for the sake of simplicity.

[*18] A similar diagram is found in Kraay and McKenzie (2014, Figure 3, with $k-y$ space).

such that $sf_j(k) + (1-\delta)k > k$ for $k \in (k_2, k^*)$, with $k^* > k_2$ is a fixed point $k^* = sf_j(k^*) + (1-\delta)k^*$. Under these assumptions, decreasing returns ensure there exists two intersections between the steady state line, one unstable and one stable equilibria.[*19]

In light of this argument, a loan that is larger than k_2 allows individuals in the goat equilibrium to transition to cattle production and arrive at the cattle equilibrium. If the lending market is competitive, the interest rate is the same as the return on capital and thus lending, not a transfer, suffices for the transition, so long as the upperbound of the loan size is no smaller than k_2. The entire region depicted in the diagram is considered as in the realm of poverty, so it shows a poverty trap within poverty (i.e., goat as ultra poor and cattle as moderately poor).

In the empirical section, we followed Bandiera et al. (2017) and took the production nonconvexity as given and interpreted the lower repayment rates and smaller cattle holding for a smaller upfront loan size as evidence consistent with a poverty trap.

IX Conclusion

Conclusion

- Entrepreneurship is necessary for project success, even with a simpler production process.
- Upfront liquidity increases asset holding and repayment rates.
- Cattle has higher returns and lower risks, resulting in higher repayment rates, but also has larger initial fixed costs, possibly generating a poverty trap.
- Lending uptake is impeded by small household size, asset shocks, and a lack of supports for managerial capacity.
- If these are relaxed, a poverty trap may be overcome.
- In the remote rural setting, larger upfront loan suited to the project cash flow is shown to be Pareto improving, despite widely believed fears of inefficiency due to information asymmetry.
- Consumption and labour incomes were not affected in non-traditional arms. Labour incomes increased toward the end of repayment for all arms which can be a repayment effort.
- Schooling was not affected in general. It finds a sign of a loss to college level women, hinting a domestic labour constraint in cattle production. But there was also a positive impact for women at the college level in WithGrace arm. While these are possibilities, cell sample sizes are too small to draw anything conclusive.

The poverty reduction impacts of microfinance was a firm belief in the early days of microfinance. Yet it suffered from a puzzling weak spot that microfinance is slow to reach the ultra poor, which is still debated today. Recently, even the poverty reduction impacts are subject to doubts, and it has been shown that the only borrowers with experience or skills are able to leap benefits. In this study, we examined the role of entrepreneurship in leaping benefits. We showed, under the rural setting, experiences or entrepreneurship seem to matter for participation and resulting impacts. We note the usefulness of having consulting services available for the prospective clients of MFIs when expanding the credit to the ultra poor.

[*19] In Figure 9, depreciation below $\underline{k}$ is not accounted as capital cannot be negative. Once the production starts for $k > \underline{k}$, the contour shows net of depreciation so $sf(k) + (1-\delta)k$.

This study employs a stepped-wedge design of multiple arms to isolate different functional attributes of loan contract: Frontloading, a grace period, and in-kind loan with management supports. These map to a liquidity constraint, a saving constraint, and an entrepreneurship constraint. Only frontloading the disbursement matters in all outcomes, which signifies the importance of a liquidity constraint. With evidence that borrowers with frontloaded arms invested in cattle while the borrowers under incremental lending invested in multiple, smaller projects, and the repayment rates are higher for the frontloaded arms, we conclude that there is a poverty trap which cannot be overcome by the traditional approach of microfinance. Under the study's setting, escaping from the poverty trap requires frontloading the lending, not lending incrementally as practiced by the majority of microfinance institutions. In addition, lending rather than a transfer may suffice to support the transition.

While we did not observe impacts of managerial supports, we found that more members with disadvantaged background participated. This implies that managerial supports can invite more disadvantaged prospective borrowers without adversely affecting the outcomes. To expand the coverage to the ultra poor, it may be useful to have consulting services.

We have witnessed that a binding domestic capacity constraint may impede potential borrowers from participation. This limits the potential benefit of lending a larger amount from the start of the program. While it in unclear why the outsourced labour cannot substitute the domestic labour, one can consider organising an arrangement in each group, tended by the group members, to collectively graze the cattle during the daytime. This partly eases the domestic labour and/or space constraints faced by small households.

We note that our study site is rich in rainfall, giving more advantages to cattle production over sheep/goat production. In contrast, if the climate is more arid, sheep and goats are better suited because of less water logging and their greater viability in relying on natural grass. This raises a concern that our results may not directly transferrable to more arid areas. However, the greater point of the lesson from the study is the presence of fixed inputs in scaling the herd size. While sheep/goats are easier to scale than cattle, it will require larger land and roofed facilities at some point. This can effectively form nonconvexity in the production set, and large enough lending may allow herders to go pass the threshold.

We have seen that borrowers accumulated assets, increased labour supplies, but not increasing the consumption. This is consistent with a high morale of repayment, which can partly be explained by the lack of alternative lenders in the study area. With stronger incentives to repay, the evidence on stronger repayment discipline of large sized arm members need not generalise in the areas outside the study site. On the other hand, the necessity of codifiable knowledge in participation even for a simple production process and the scope for escaping the poverty trap with large, frontloaded lending may be more generalisable to other rural areas that are suited to livestock production.

A Data description

TABLE A1: DESCRIPTIVE STATISTICS BY ARM IN ADMINISTRATIVE DATA

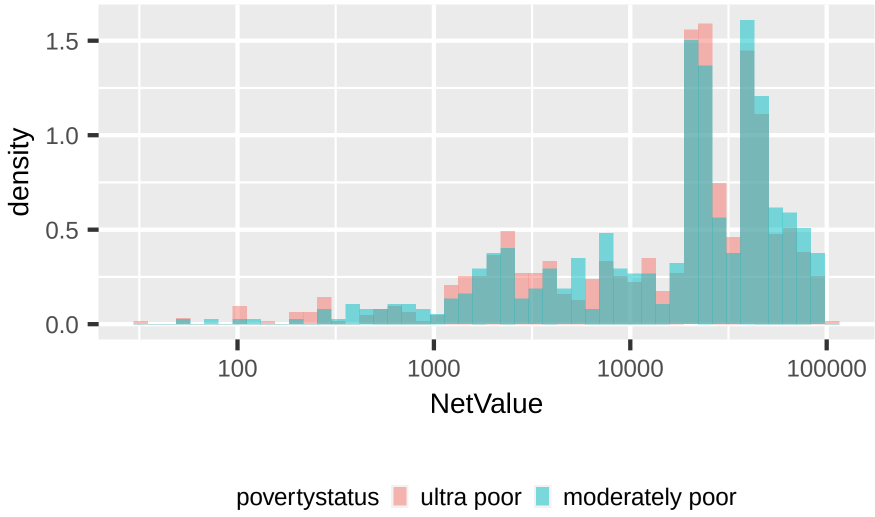
variables	traditional	large	large grace	cow
Head Literacy	0.11	0.14	0.10	0.13
Head Age	37.96	38.12	38.66	37.86
Household size	4.37	4.08	4.17	4.08
Flood in round 1	0.58	0.50	0.36	0.55
Net saving (% of loan) in 2013	3.45	4.02	5.49	6.70
Effective Repaymentment in Loan Year -1	165.45	517.45	567.27	565.26
Effective Repaymentment in Loan Year 1	403.33	493.44	212.63	211.66
Effective Repaymentment in Loan Year 2	179.06	320.09	499.23	455.44
Effective Repaymentment in Loan Year 3	248.21	382.42	566.32	535.22
Effective Repaymentment in Loan Year 4	345.50	314.41	282.75	350.22
Repayment in Loan Year -1	55.19	38.93	0.00	0.00
Repayment in Loan Year 1	352.96	420.63	42.87	37.67
Repayment in Loan Year 2	139.43	272.92	463.21	420.32
Repayment in Loan Year 3	206.11	338.97	538.29	505.76
Repayment in Loan Year 4	318.00	291.86	270.47	333.69
Number of loan receiving members	116	180	180	190

Source: Estimated with GUK administrative and survey data.

Notes: 1. Information of original 800 households. Net saving as percentage of loan amount is a mean over loan recipients whose first disbursement is in 2013. Effective repayment is a sum of repayment and net saving.

2. Loan year -1 is preparation period for loan disbursement when only saving is allowed.

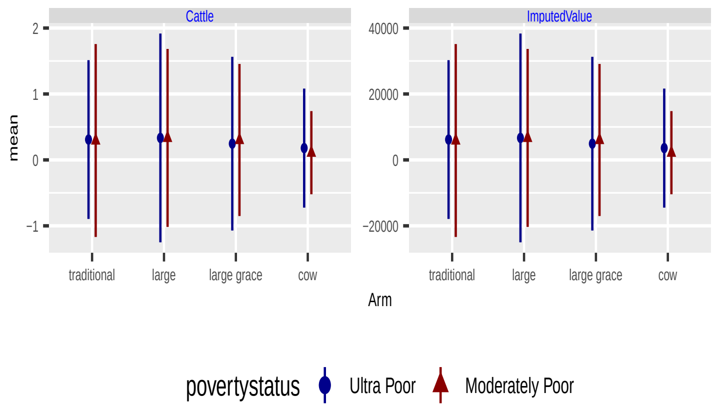
Figure A1: Net asset values at baseline



Source: Survey data.

Note: Net asset values = total gross asset values - debt outstanding. Debt outstanding takes the value of the month immediately after the respective survey round interview.

Figure A2: Livestock holding at baseline



Source: Survey data.

Note: Livestock holding at baseline. Median market price is used to convert holding to values.

Notes: 1. R's package coin is used for baseline group mean covariates to conduct approximate permutation tests. Number of repetition is set to 100000. Number of groups is 72. Step-down method is used to adjust for multiple testing of a multi-factor grouping variable.

2. ***, **, * indicate statistical significance at 1%, 5%, 10%, respetively. Standard errors are clustered at group (village) level.

Source: Survey data.

Note: Each column uses respective year cattle ownership information. For ANOVA and Kruskal-Wallis, each entry indicates p values. ANOVA tests for the null of equality of means under normality. Kruskal-Wallis tests for the null of no stochastic dominance among samples without using the normality assumption. Tukey's honest significant tests show difference in means and p values in parenthesis that account for multiple testing under normality. In column 2, we edited data by assigning 1 to members of cow arm at dates after disbursement if reported holding is NA or zero.

C Rejection

Among 800 observations, there are 4 whose villages are washd away and 70 who by group rejected the assigned arms which are traditional, large, large grace with 40, 20, 10, 0 individuals, respectively. There are 31, 9, 13, 37 individuals who individually rejected traditional, large, large grace, cow, respectively. Among attrited HHs, when were they lost?

Table ?? to Table ??: Trimmed sample.

Table C1 shows test results of independence between loan receivers and nonreceivers (group, individual rejecters) on the analysis sample of 776 members. It shows that lower head literacy, smaller household size, being affected by flood at the baseline, smaller livestock holding, and smaller net assets are correlated with opting out the offered type of lending. Table C2 indicates that lower asset and livestock holding is more pronounced among traditional rejecters relative to loan receivers. It also shows that flood exposure is less frequent, contrary to Table C1, among the rejecters. Table C3 indicates that lower head literacy, smaller household size, higher flood exposure, are more pronounced among non-traditional rejecters relative to loan receivers. It also shows that asset and livestock holding is no different relative to the receivers. Comparing rejecters of traditional arm, lower flood exposure may be the only stark difference against non-traditional arm members, and smaller asset and livestock holding is merely suggestive (Table C4).

Group rejecters and non-group rejecters are compared in Table C5. Marked differences are found in arm (traditional vs. non-traditional) and net asset values and head literacy are noted. Table C6 compares group rejecters in traditional arm and finds smaller flood exposure and lower livestock and net asset holding are associated with group rejection. Group rejecters in non-traditional arm are examined in Table C7 and younger head age, flood at baseline, and smaller household asset holding are correlated with rejection. Comparing group rejecters between traditional and non-traditional arms in Table C8, younger head age, higher flood exposure, larger net asset values and livestock holding are noted among the non-traditional group rejecters. These hint that for non-traditional arm group rejecters, it is the smaller household size and the baseline flood that may have constrained them from participation, and for traditional group rejecters, it is the low asset levels.

Acknowledging the reasons for rejection can be different, we tested the independence of each characteristics for individual rejecters (vs. non-individual rejeceters) in Table C9. Smaller HHsize, being affected with FloodInRd1, and smaller LivestockValue, NumCows, and NetValue are associated with individual rejecters. Individual decisions not to participate may be more straightforward: Smaller household size may indicate difficulty in securing the cattle production labour in a household, being hit with a flood may have resulted in lower livestock levels that would prompt them to reconsider partaking in another livestock project.

Table C10 and Table C11 compare individual rejecters and nonrejecters in traditional arm and non-traditional arms, respectively. For traditional rejecters, livestock and other asset values are not correlated with rejection, but the values are similar to non-traditional and higher p values may be due to smaller sample size. For non-traditional arm rejecters, household size and flood exposure are correlated. Comparison of individual rejecters between traditional and non-traditional arms show no detectable difference (Table C12). This suggests that indvidual rejecters in all arms were constrained with small household size and small asset holding.

TABLE D1 shows results from tests of independence between attriters and non-attriters. We see the moderate rate of attrition is not correlated with household level characteristics at the conventional p value level. Productive asset amounts seem to differ between attriters and non-attriters, with the former being larger than the latter. This positive attrition selection can cause underestimation of impacts, if the asset values are positively correlated with entrepreneurial capacity. TABLE D2 shows attrition in the traditional arm. Household heads of attriters are relatively less literate than non-attriters. TABLE D3 compares attriters and non-attriters in the non-traditional arm. Unlike traditional arm attriters, non-traditional arm attriters have more literate household heads, have a larger household size, are more exposed to floods, and have larger productive assets. The traditional arm attriters may be less entrepreneurial, if anything, so their attrition may upwardly bias the positive gains of the arm, hence understate the impacts of non-traditional arm. These are explicitly shown in TABLE D4 where we compare attriters of traditional and non-traditional arms. Overall, attrition may have attenuated the impacts but is not likely to have inflated them.[*20]

TABLE D5 picks up only program surviving members (nonattrited and loan recepients) have greater asset values than non-survivors. Comparing the surviving members, characteristics are similar except that the traditional members are more exposed to the flood than the non-traditional members. Comparing against the large grace arm, survivors in the cattle arm are more exposed to the flood, have fewer productive assets, and have less livestock with p value at .124 (TABLE D6). This shows that the smaller livestock holders are encouraged to participate and continue to operate in the cattle arm that has a managerial support program with all other features being equal. This underscores our intrepretation that the current impact estimates may be downward biased, if any, as people who would otherwise attrit or reject in cattle arm stayed on.

Moved from main text.

Group rejecters of traditional and non-traditional arms differ in household characteristics. Lower livestock values, smaller cattle holding, and smaller net asset values are associated with group rejection for traditional arm (TABLE C6), while higher baseline flood exposure rates and younger household heads are associated with group rejection for non-traditional arms (TABLE C7). Given randomisation, we conjecture that it is lack of Upfront liquidity that prevented smaller livestock holders of traditional arm from participating because they cannot purchase cattle due to insufficient net asset values or an insufficient resale value of owned livestock, when members of similar characteristics partcipated in non-traditional arms. For non-traditional arm rejecters, it is the past flood that kept members from participating, even they are younger and have similar cattle holding as the non group-rejecters.

Individual rejecters of traditional arm and non-traditional arms share similar characteristics (TABLE

[*20] So one can employ the Lee bounds for stronger results, but doing so will give us less precision and require more assumptions. We will not use the Lee bounds [we can show them if necessary].

C12). In fact, they are not very different in all the variables considered. The common factors associated with nonparticipation are a smaller household size and smaller livestock holding (Table C10 and Table C11), although the p values for livestock holding difference between individual rejecters and non individual rejecters are around 7% (Table C9).

Source: Estimated with GUK administrative and survey data.

Notes: 1. ANCOVA estimates using administrative and survey data. Post treatment regressands are regressed on categorical variables, pre-treatment regressand and other covariates. Time invariant household characteristics (head age and head literacy) are taken from baseline housheold survey data. Sample comprises of (1) continuing members, and (2) replacing members of early rejecters who received a loan prior to Janunary, 2015. Large, LargeGrace, Cattle are indicator variables of the large, large grace, and cattle arms, respectively. The default arm category is traditional arm. Household assets do not include livestock. Regressions (1)-(3), (5)-(6) use only arm and calendar information. (4) and (7) use previous six month repayment and saving information which is lacking in rd 1, hence starts from rd 2.

2. P values in percentages in parenthesises. Standard errors are clustered at group (village) level.

Notes: 1. ANCOVA estimates using administrative and survey data. Post treatment regressands are regressed on categorical variables, pre-treatment regressand and other covariates. Time invariant household characteristics (head age and head literacy) are taken from baseline housheold survey data. Sample comprises of (1) continuing members, and (2) replacing members of early rejecters who received a loan prior to Janunary, 2015. Upfront is an indicator variable of the arm with an upfront large disbursement, WithGrace is an indicator variable of the arm with a grace period, InKind is an indicator variable of the arm which lends a heifer. Household assets do not include livestock. Regressions (1)-(3), (5)-(6) use only arm and calendar information. (4) and (7) use previous six month repayment and saving information which is lacking in rd 1, hence starts from rd 2.

2. P values in percentages in parentheses. Standard errors are clustered at group (village) level.

Table E3: ANCOVA estimation of cattle holding by arm and period

covariates	mean/std	(1)	(2)	(3)	(4)

Source: Estimated with GUK administrative and survey data.

Notes: 1. ANCOVA estimates using administrative and survey data. Post treatment regressands are regressed on categorical variables, pre-treatment regressand and other covariates. Time invariant household characteristics (head age and head literacy) are taken from baseline housheold survey data. Sample comprises of (1) continuing members, and (2) replacing members of early rejecters who received a loan prior to Janunary, 2015. Upfront is an indicator variable of the arm with an upfront large disbursement, WithGrace is an indicator variable of the arm with a grace period, InKind is an indicator variable of the arm which lends a heifer. rd2, rd3, rd4 are dummy variables for second, third, and fourth round of survey. Labour incomes are in 1000 Tk units and are a sum of all earned labour incomes of household members. Farm revenues are in 1000 Tk units and are a total of agricultural produce sales.

2. P values in percentages in parenthesises. Standard errors are clustered at group (village) level.

Source: Estimated with GUK administrative and survey data.

Notes: 1. ANCOVA estimates using administrative and survey data. Post treatment regressands are regressed on categorical variables, pre-treatment regressand and other covariates. Time invariant household characteristics (head age and head literacy) are taken from baseline housheold survey data. Sample comprises of (1) continuing members, and (2) replacing members of early rejecters who received a loan prior to Janunary, 2015. Upfront is an indicator variable of the arm with an upfront large disbursement, WithGrace is an indicator variable of the arm with a grace period, InKind is an indicator variable of the arm which lends a heifer. Secondary and College are indicator variables of secondary schooling (ages 13-15) and tertiary schooling (ages 16-18), both at the time of baseline. Default category is primary (ages 05-12). rd2, rd3, rd4 are dummy variables for second, third, and fourth round of survey. Interaction terms of dummy variables are demeaned before interacting. The first column gives mean and standard deviation (in parenthesises) of each covariates before demeaning.

2. *P* values in percentages in parenthesises. Standard errors are clustered at group (village) level.

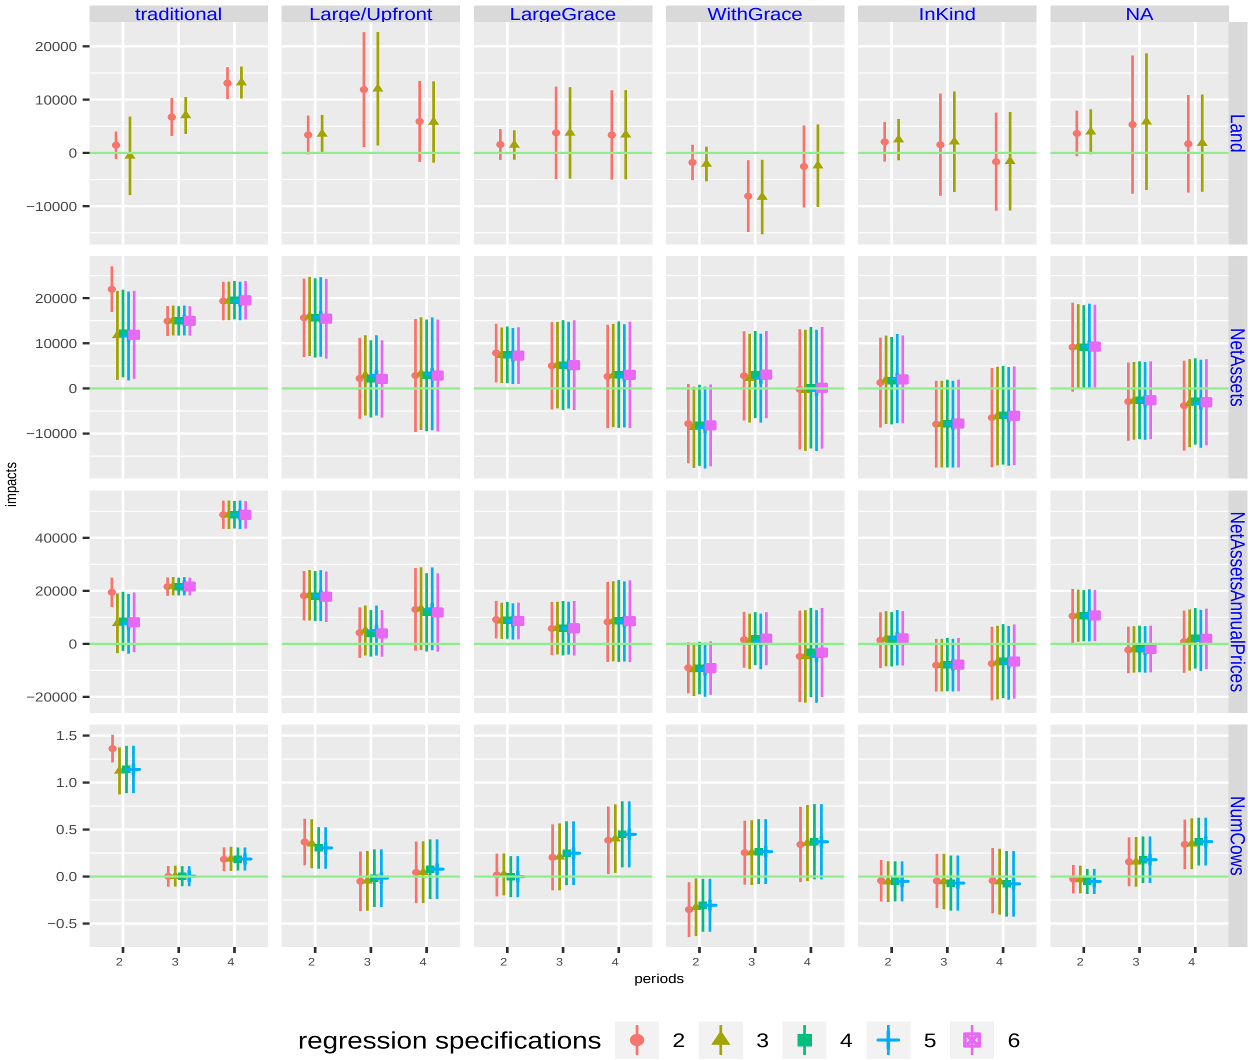
Notes: 1. ANCOVA estimates using administrative and survey data. Post treatment regressands are regressed on categorical variables, pre-treatment regressand and other covariates. Time invariant household characteristics (head age and head literacy) are taken from baseline housheold survey data. Sample comprises of (1) continuing members, and (2) replacing members of early rejecters who received a loan prior to Janunary, 2015. Upfront is an indicator variable of the arm with an upfront large disbursement, WithGrace is an indicator variable of the arm with a grace period, InKind is an indicator variable of the arm which lends a heifer. Secondary and College are indicator variables of secondary schooling (ages 13-15) and tertiary schooling (ages 16-18), both at the time of baseline. Default category is primary (ages 05-12). rd2, rd3, rd4 are dummy variables for second, third, and fourth round of survey. Interaction terms of dummy variables are demeaned before interacting. The first column gives mean and standard deviation (in parenthesises) of each covariates before demeaning.

2. P values in percentages in parenthesises. Standard errors are clustered at group (village) level.

Figure E3: Effects on land, livestock, and net assets



Source: Constructed from ANCOVA estimation results.

Note: Left most column panel shows the conditional means of traditional arm which serves as a benchmark in estimating impacts. In other column panels, all points show the relative difference from concurrent traditional levels depicted in the left most column. Large and Upfront are the same values. Other column panels are grouped either by arm or by attribute. Row panels show different outcomes. Bars show 95% confidence intervals using cluster robust standard errors.
